# PHOSPHINIMINES AS POTENTIAL 

TECHNETIUM
ENVIRONMENTAL SENSORS

A Dissertation presented to the Faculty of the Graduate School
University of Missouri-Columbia

In Partial Fulfillment of the
Requirements for the Degree

Doctor of Philosophy
by
LEAH M. ARRIGO

Dr. Silvia Jurisson, Dissertation Supervisor
MAY 2007

The undersigned, appointed by the Dean of the graduate School, have examined the dissertation entitled

# PHOSPHINIMINES AS POTENTIAL <br> TECHNETIUM <br> ENVIRONMENTAL SENSORS 

Presented by Leah M. Arrigo

A candidate for the degree of Doctor of Philosophy
And hereby certify that in their opinion it is worth of acceptance.

| Dr. Silvia Jurisson |
| :---: |
| Dr. Raghraman Kannan |
| Dr. William H. Miller John D. Robertson |
| Dr. Sheryl Tucker |
| Dr. Paul Sharp |

"Fear not, for I am with you; be not dismayed, for I am your God. I will strengthen you, yes, I will help you, I will uphold you with My righteous right hand." Isaiah 41:10
"I can do all things through Christ with strengthens me." Philippians 4:13

This work would not be possible without the strength, patience, and perseverance the Lord has bestowed. The glory belongs to Him alone.

I would like to further dedicate this dissertation to my mother, Ellen Russell. Without her time, patience, and support it would not have been possible. I would also like to thank the rest of my family - my father Glen Russell, brother Jacob Russell, and sister Laura Russell.

## ACKNOWLEDGMENTS

I would like to express my appreciation and gratefulness to my advisor, Dr. Silvia Jurisson. She not only allowed me to join her research group after leaving another group but without her advice, direction, and support this dissertation would not be possible. I have learned a tremendous amount from her. I would also like to express my appreciation to Dr. Raghuraman Kannan. Dr. Kannan taught me about phosphorous chemistry and gave much direction on the synthesis portions of the project. I am grateful that Dr. Kannan and Dr. Kattesh Katti allowed me to work in their group and gave up their time and resources to help me. I am thankful to both my group members in the Jurisson research group and in the Katti research group. Their input and knowledge were extremely helpful and useful. Miss Miriam Galenas worked as an undergraduate researcher on this project with me and I am very thankful to have had her help. It was extremely valuable both to mentor her and to have her assistance in the laboratory.

Dr. Sheryl Tucker and Daniel Bassil both contributed to the taking of the fluorescence measurements and interpretation of the data. Without their assistance and support that portion of the project would not have been possible. I would like to thank Dr. Charles Barnes for obtaining the X-ray crystal structures, Wei Wycoff for helping us perform ${ }^{99}$ Tc NMR and long ${ }^{31}$ P NMR experiments, and Dr. Nathan Leigh for obtaining the mass spectra of the compounds.

I would also like to thank several individuals who did not contribute directly to the project but without whom it would not have been possible. Dr. William Miller provided considerable time and expertise. I learned a lot as a teaching assistant for him and having him as an instructor. He has given his support throughout my graduate
studies. Dr. Paul Duval was a significant influence on this dissertation. As my first research advisor, he taught me airfree synthesis techniques and gave me direction and assistance even with changing research groups.

I would like to thank the Department of Chemistry and the Nuclear Sciences and Engineering Institute for providing funding to complete this project.

# PHOSPHINIMINES AS POTENTIAL TECHNETIUM ENVIRONMENTAL SENSORS 

Leah M. Arrigo

Dr. Silvia S. Jurisson, Dissertation Supervisor

#### Abstract

Phosphinimines, $\mathrm{R}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$, undergo hydrolysis to form the phosphiniminium cation, $\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$, which forms the ion pair $\left[\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{X}^{-}\right]$in the presence of an anion. Preliminary studies show that in the presence of $\mathrm{TcO}_{4}{ }^{-}, \mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ forms $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$and $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]$is selective for $\mathrm{TcO}_{4}{ }^{-}$over other anions. Technetium-99 is present as environmental contamination in the form of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$, which is extremely mobile. Currently available methods to measure this contamination are time consuming and tedious. A method to preconcentrate and measure ${ }^{99}$ Tc environmental contamination in a quick and efficient manner is needed. The selectivity of the phosphiniminium cation for $\mathrm{TcO}_{4}{ }^{-}$may make phosphinimines suitable for such preconcentration and possibly for measurement. Several phosphinimines were synthesized and characterized for their stability and selectivity with ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$, including $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ and (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ include possible reporter groups and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ contains a linking moiety for incorporating reporter groups or attaching the phosphinimine to a polymer support. The use of internal and external reporter groups to generate a signal in the presence of $\mathrm{TcO}_{4}{ }^{-}$is also investigated.

## CHAPTER 1: INTRODCUTION

### 1.1 Origin of environmental radioactive contamination

### 1.1.1 The History and use of radioactivity

The twentieth century was a time of technological leaps for the fields of nuclear and radiochemistry. The first radioactive emissions were captured by Henri Becquerel in 1896 as he accidentally exposed photographic plates to uranium, which resulted in Becquerel, Marie Curie, and Pierre Curie receiving the 1903 Nobel Prize for the discovery of radioactivity. James Chadwick discovered neutrons in 1932 making possible the discovery of fission in 1938 by Lise Meitner, Otto Hahn, and Fritz Straussmann. By 1939, Germany had begun work on the military use of fission technology. With the threat of a German victory in World War II, the United States and Great Britain began work on the nuclear bomb. The Manhattan Project formally began in 1942 with the first reactor and reprocessing plant built and in operation at the Hanford site in Washington State by 1944, less than two years after Enrico Fermi and his team at the University of Chicago demonstrated that a controlled nuclear chain reaction was possible. The urgent need for success due to World War II and the use of untested technology led to radioactive contamination of the environment that continues today. ${ }^{1}$

Due to the necessity of secrecy for portions of the Manhattan Project and for the protection of citizens, numerous nuclear sites were developed, each with its specific function. Examples include Hanford, Washington (the production of plutonium for nuclear bombs); Savannah River, South Carolina (the production of plutonium for nuclear bombs); Rocky Flats, Colorado (manufacture of plutonium bomb-triggers); and Fernald Feed Materials Production Center, Ohio (uranium processing). A total of 16
major facilities across the United States researched, manufactured, assembled, and tested nuclear materials and bombs. ${ }^{2}$ All of these sites have some form of environmental contamination, dependant on their specific function. The site located at Hanford, Washington is one of the most well-known due to the pervasiveness of the contamination. Ground was broken for the 640 square-mile Hanford site in March of 1943. ${ }^{1}$ This site was chosen for its sparse population, location adjacent to a major water source for cooling the nuclear reactors (Columbia River), and for the quality of the soil. By late 1944, billions of gallons of liquids and billions of cubic meters of gases were being emitted from the plants. ${ }^{1}$ A total of eight single-pass / open-coolant reactors were built over the life-span of the site. The first reactor, B-reactor, went critical in September 1944. Plutonium was produced and reprocessed in significant quantities by February 1945. The reactors contained mainly ${ }^{238} \mathrm{U}$, which when bombarded with neutrons of the correct energy, absorbed a neutron to generate ${ }^{239} \mathrm{U}$. This then beta decayed to produce ${ }^{239} \mathrm{Pu}$, a fissionable material. The reactor fuel was then reprocessed to isolate the plutonium for manufacturing the nuclear bombs. The byproducts of the process when ${ }^{235} \mathrm{U},{ }^{238} \mathrm{U}$, or ${ }^{239} \mathrm{Pu}$ undergoes fission are called "fission products." These fission products include a wide variety of radionuclides with a variety of half-lives. The radionuclides produced in larger quantities with sufficiently long half-lives to be of continual concern include ${ }^{99} \mathrm{Tc},{ }^{137} \mathrm{Cs}$, and ${ }^{90} \mathrm{Sr}$.

### 1.1.2 River Pollution

By 1955 there were eight single-pass / open-coolant reactors operating at
Hanford. ${ }^{1}$ The coolant in these reactors was water from the Columbia River. River water
was pumped into the reactors to remove excess heat that would otherwise damage the reactor. The hot water was then dumped back into the river after a single pass through the reactor core. Coolant water must be very pure to avoid making the impurities radioactive while it was inside the reactor; the engineers at Hanford thought the Columbia River was a perfect source since it was already sufficiently pure. The reactors were all experimental and the first of their kind; the fuel rods broke and cracked under the high temperature and radiation. This exposed kilograms of uranium and fission products in each fuel rod to river water, dissolving the radioactive and hazardous chemicals in the fuel. ${ }^{2}$ By December 1946, an estimated 40,000 Ci had been released in the reactor coolant - a discharge rate of $1,500 \mathrm{Ci} /$ month. ${ }^{1}$ This was a decrease from the peak of 900 $\mathrm{Ci} /$ day. ${ }^{1}$ Radionuclides of immediate concern were ${ }^{32} \mathrm{P},{ }^{76} \mathrm{As},{ }^{65} \mathrm{Zn},{ }^{51} \mathrm{Cr}$, and ${ }^{239} \mathrm{~Np}$; all were beta-emitters that affect the GI tract, bones, reproduction, and blood-formation. ${ }^{1}$ These radionuclides were found in shellfish at the mouth of the Columbia River, which is a principal hatchery and fishery for salmon and steelhead trout. ${ }^{1}$ The fish downstream of the Hanford site contained $100,000-170,000$ times the radioactivity of the fish upstream that had not been exposed to water from the reactors. ${ }^{1}$ Most of the radioactivity was contained in the liver, kidneys, and muscle tissue; the radionuclides included ${ }^{32} \mathrm{P},{ }^{76} \mathrm{As}$, ${ }^{65} \mathrm{Zn},{ }^{51} \mathrm{Cr}$, and ${ }^{239} \mathrm{~Np}$. Studies done in 1975 found long-lived radionuclides in river sediments, an estimated 1000 Ci of ${ }^{65} \mathrm{Zn}, 4000 \mathrm{Ci}$ of ${ }^{60} \mathrm{Co}, 2000 \mathrm{Ci}$ of ${ }^{152} \mathrm{Eu}, 3000 \mathrm{Ci}$ of ${ }^{3} \mathrm{H}, 10,000 \mathrm{Ci}$ of ${ }^{99} \mathrm{Tc}$, and $<1000 \mathrm{Ci}$ of other radionuclides. ${ }^{1}$ As aquatic life, algae, insects, and fowl drank the river water and ate plants that have incorporated river water, the radionuclides traveled up the food chain and became more concentrated, up to
hundreds of thousands of times. ${ }^{1}$ The eight single-pass reactors were shutdown between 1964 and $1971 .{ }^{1}$

### 1.1.3 Groundwater Pollution

When selecting the Hanford site, the scientists and engineers believed that the sand and gravel soil was nearly ideal for disposal of radioactive wastes. ${ }^{1}$ The soil at Hanford contains sand and gravel, and sits on the Touchet Formation, glacial outwash sands, gravels, and fine volcanic ash that average 100-250 ft. This then sits on the Ringold Formation of silt, clay, and wind-deposited Palouse soils approximately 1,200 ft thick. The deepest layer is a basalt plateau. ${ }^{1}$ The groundwater is in a number of confined and unconfined aquifers interspersed with basaltic ridges. ${ }^{1}$ Water enters either the Columbia River to the southeast or the Yakima River to the southwest. The groundwater level varies from a few feet below the surface to 300 feet. ${ }^{1}$

Millions of curies of radioactivity were directly released into the Columbia River, air, and soil of the Columbia Basin. ${ }^{1}$ Disposal of the low-level $\left(<5 \times 10^{-5} \mu \mathrm{Ci} / \mathrm{mL}\right)$ and intermediate-level ( $5 \times 10^{-5}$ to $100 \mu \mathrm{Ci} / \mathrm{mL}$ ) wastes involved pouring them on the ground in trenches, pools, and cribs. ${ }^{1}$ The releases totaled millions of gallons each day. ${ }^{1}$ Contrary to what the scientists believed, the radionuclides did not adsorb to the soil. Rather, they passed through the top layer of sand and gravel, through the Touchet Formation, and into the Ringold Formation. The radionuclides are still mobile in this layer, but less so than in the layers above it. The groundwater, however, is either in this layer or above it. Additionally, there are large differences in the types and coarseness of the sand and gravel soil such that the radionuclides migrated differently in different
locations thus complicating matters. ${ }^{1}$ Once the soil that contained the radioactive waste dried, the wind carried the soil contaminated with dry radionuclides to the surrounding areas. ${ }^{1}$ To prevent the dry soil from being blown away by the wind, "reverse-wells" were used. These were dry shafts for low-level liquid waste; however, this only allowed the waste to get closer to the water table. ${ }^{1}$ The radionuclides of particular concern for both inhalation and groundwater contamination included ${ }^{99} \mathrm{Tc},{ }^{90} \mathrm{Sr},{ }^{137} \mathrm{Cs},{ }^{144} \mathrm{Ce},{ }^{129} \mathrm{I},{ }^{91} \mathrm{Y}$, ${ }^{152} \mathrm{Eu},{ }^{154} \mathrm{Eu},{ }^{239} \mathrm{Pu}$, and ${ }^{238} \mathrm{U} .{ }^{1}$ In 1945, wells present on site were contaminated with uranium and it had spread offsite to wells at Benton City by mid 1947. ${ }^{1}$ By 1956, ${ }^{60} \mathrm{Co}$ was found in the groundwater beneath Hanford. ${ }^{1}$ The total volume released to the soil is estimated at 120 billion gallons, containing 3.2 million Ci of beta-emitters, $280,000 \mathrm{~g}$ of plutonium, and $120,000 \mathrm{~kg}$ of uranium. ${ }^{1}$

Table 1: Radionuclides of concern for inhalation and groundwater contamination ${ }^{3}$

| Radionuclide | Half-life $\left(\mathrm{t}_{1 / 2}\right)$ | Decay Mode | Energy (MeV) | Potential Hazard |
| :---: | :---: | :---: | :---: | :---: |

### 1.1.4 Underground tanks

Due to the urgency to produce sufficient plutonium for the war needs, the Hanford site did not initially reprocess fuel or treat radioactive or hazardous waste. Several tank farms were built from 1943 to 1985. There are a total of 177 cylindrical underground storage tanks ranging in capacity from 55,000 to 1.1 million gallons. ${ }^{2}$ The tanks contained 54 million gallons of hazardous and radioactive waste as of 1998. ${ }^{2}$ The first tanks built were single-shell; there was a single carbon steel wall and floor covered by a dome and outer shell of concrete. ${ }^{2}$ Beginning in 1968, double-shell tanks were constructed; these contained two carbon steel liners and a single steel dome liner with the entire tank encased in reinforced concrete. ${ }^{2}$ A total of 149 single-shell tanks and 28 double-shell tanks were constructed at the site ${ }^{2}$ out of carbon steel rather than stainless steel, and the pipes were caste-iron ${ }^{1}$ due to cost considerations. The waste was made alkaline by the addition of large volumes of sodium hydroxide in an attempt to prevent corrosion of the tanks. This was not successful, and 68 tanks are known or suspected of leaking at least 1 million gallons of waste into the soil and groundwater. ${ }^{1}$ The groundwater below the tank farms eventually flows into the Columbia River. ${ }^{2}$

The first leak was suspected in 1956 and confirmed in 1961 from tank 104-U. ${ }^{2}$ Cleaning up the tanks is made more difficult by the fact that the contents of the tanks are heterogeneous, and that across tanks the contents are different. ${ }^{4}$ The tank contents include a sludge at the bottom comprised of insoluble residues, solid excess salt, and precipitated residues; next is a residual liquid saturated with salt and suspended salt crystals; and on the top is a floating crust of low-density salts. ${ }^{4}$ Each tank also contains different radionuclides and different chemicals depending on when the waste was
generated (several different processes were used), what was added to the tank in an attempt to stabilize it, and whether it was mixed with any other tank contents. Cleaning up the tank waste is a process that has been ongoing with no end in sight. Thus waiting to clean up the tanks before tackling the groundwater and soil contamination is not an option. The groundwater and soil contamination continues to increase and to migrate.

Contamination to the environment came first from the known release of radioactive coolant water and radioactive waste to the Columbia River, ground, and air. It now continues to come from the aging and leaking underground tanks.

### 1.1.5 Evidence of contamination at other nuclear sites ${ }^{1}$

Each site developed during the Manhattan Project has environmental contamination with radionuclides and/or hazardous chemicals related to its specific function. Not all the sites possess ${ }^{99} \mathrm{Tc}$ contamination.

- Hanford, WA - Released millions of gallons of low-level radioactive waste to the ground each day, released radioactive gases into the atmosphere. Underground tank farms were leaking beginning in the 1950s. The river, river sediment, soil, and groundwater surrounding the Hanford site is thoroughly contaminated with radionuclides as well as harmful chemicals. ${ }^{1}$
- Savannah - By the 1950s there were five weapons-production reactors and two River Site, chemical reprocessing plants. The site and the reactors were SC shutdown by the late 1980s due to safety concerns and violations -
broken and disengaged radiation-monitors, disconnected sprinklers, geological fault under the site. Savannah River Site also contains a tank farm for storage of radioactive wastes. ${ }^{1}$
- Rocky Flats, CO
- Plutonium and toxic chemicals were released to the air and soil during the 35 years of operation. The DOE was forced to buy land adjacent to the site as a buffer zone, and it went from the original 10 square-miles to thousands of acres. In 1988, employees and a DOE inspector inhaled radioactive particles. Inspectors found uncalibrated radiation-monitors, antiquated fire-alarm systems, and toxic wastes leaching into the groundwater. The site is 16 miles from Denver. ${ }^{1}$
- Fernald Feed - The 1050 acre uranium-processing complex operated from 1952 until 1986. The site was shut down in December 1984 and it was found that excessive amounts of uranium dust and oxides had been Center, OH released through ventilation systems. Approximately 230 tons of radioactive material had leaked into the Greater Miami River valley over 30 years; 337 tons of $\mathrm{UF}_{6}$ could not be located; thousands of kilograms of uranium dust vented to the atmosphere and surface water; 5 million kilograms of radioactive and hazardous substances were released to pits and swamps and then into the groundwater; 200,000 canisters and barrels with mixed and hazardous wastes could not be identified. The State of Ohio was
awarded $\$ 1$ million and oversight for the cleanup. The local population was awarded $\$ 78$ million for lost property values and health needs. ${ }^{1}$
- Idaho - A total of $\$ 456$ million was awarded for 5.5 years to cleanup National buried waste. ${ }^{1}$

Engineering
Laboratory

- Oak Ridge - There was a discharge of 2.4 million pounds of mercury from the

Reservation, Y-12 Nuclear Weapons Components Plant. The groundwater
TN contains polychlorinated biphenyls (PCBs), heavy metals, and radioactive substances. Toxic and radioactive wastes were allowed to drain into White Oak Creek, which feeds into the Clinch River traces of plutonium were found 40 miles downstream in $1990 .{ }^{1}$

- Pantex, TX - The site released dimethylformamide and acetone into the soil and Ogallala aquifer, a major water source for the State of Texas and neighboring states. ${ }^{1}$

### 1.2 Production of technetium

Technetium-99 is produced from the thermal neutron fission of ${ }^{235} \mathrm{U}$ and ${ }^{239} \mathrm{Pu}$ in $6 \%$ yield. Technetium-99 emits a $0.292 \mathrm{MeV} \beta^{-}$with a half-life of $2.15 \times 10^{5}$ years. Most radionuclides require approximately 10 half-lives before they can be considered to have decayed to background levels. This means that ${ }^{99} \mathrm{Tc}$ requires approximately 2 million years, before all the ${ }^{99} \mathrm{Tc}$ that has been produced to date will be considered to have
decayed. This long half-life makes ${ }^{99} \mathrm{Tc}$ a concern for long-term storage and environmental contamination.

### 1.3 Technetium in the environment

Under aerobic environmental conditions, technetium is present as $\mathrm{TcO}_{4}{ }^{-}$and is easily taken up in plants, algae, lichen, and some sea life, such as crustaceans and clams. ${ }^{5}$ $\mathrm{TcO}_{4}{ }^{-}$migrates easily through the environment due to its low negative charge, while radionuclides such as ${ }^{137} \mathrm{Cs}$ and ${ }^{90} \mathrm{Sr}$ do not. Soils contain negatively charged species such as zeolites and humic acids to which cations such as ${ }^{137} \mathrm{Cs}^{+}$and ${ }^{90} \mathrm{Sr}^{2+}$ readily sorb. The anionic $\mathrm{TcO}_{4}{ }^{-}$is repelled by these species and so migrates quickly and enters the food chain. $\mathrm{TcO}_{4}{ }^{-}$is not an ingestion hazard to humans since it is readily excreted from the body in urine. Many plants, algae, lichen, and sea life take up and retain $\mathrm{TcO}_{4}^{-}$, and then metabolize it to a more lipophilic form that does not excrete from the body, similar to that observed with mercury uptake. Between 1956 and $1981,{ }^{99} \mathrm{Tc}$ was measured in lichen and then in the reindeer that feed on the lichen. ${ }^{5}$ While people do not eat lichen, they do eat reindeer as well as sea life such as lobsters, clams, and certain fish and thus ingest and incorporate the ${ }^{99} \mathrm{Tc}$. This could pose a serious health risk and potentially cause cancer. In 1984, trees at Oak Ridge National Laboratory in Oak Ridge, TN tested positive for ${ }^{99} \mathrm{Tc}$. Burning this wood would release ${ }^{99} \mathrm{Tc}$ into the air, and animals that eat wood and nuts would ingest ${ }^{99} \mathrm{Tc}$. Technetium-99 does have a geochemical sink in anaerobic soils because it forms $\mathrm{TcO}_{2}$, which is an insoluble colloid. ${ }^{5}$ As soon as these soils are exposed to water or oxygen, $\mathrm{TcO}_{2}$ forms $\mathrm{TcO}_{4}{ }^{-}$and it again becomes mobile.

For safety and clean up purposes, there is great interest in monitoring the location and movement of this ion.

### 1.4 Sensing: Anionic, fluorescent, scintillation

The process of sensing involves the production of a qualitative or quantitative signal in the presence of a specific analyte. ${ }^{6}$ The sensor generates the signal in recognition of or binding by the analyte through characteristic and measurable properties of the analyte. ${ }^{7}$ The sensor itself generally has three components: (i) chemical receptor for the analyte, (ii) signal transduction process where the binding event is converted into a physical change, and (iii) a method of measuring the signal. ${ }^{8}$ The first and third distinguish different types of sensors: the type of analyte detected (i.e., cation, anion) and the type of signal generated (i.e. fluorescence, luminescence).

Anion sensing is the qualitative detection or quantitative determination of a negatively charged species by a device, which translates its presence into a physical signal. ${ }^{6}$ Anion sensing is less developed than cation sensing and is generally more difficult. ${ }^{8}$ Anion interactions are generally weaker than cation interactions with their respective molecules. ${ }^{6}$ Additional differences include: ionic size (anions are usually larger than cations, $\mathrm{Cl}^{-} 0.167 \mathrm{~nm}, \mathrm{~K}^{+} 0.133 \mathrm{~nm}$ about the same as $\mathrm{F}^{-}$), a number of different geometries (spherical $\mathrm{Cl}^{-}$, linear $\mathrm{CN}^{-}$, tetrahedral $\mathrm{SO}_{4}{ }^{2-}$, trigonal planar $\mathrm{NO}_{3}{ }^{-}$), and a narrower pH window with potentially variable ionization (carbonate vs bicarbonate). ${ }^{8} \mathrm{TcO}_{4}^{-}$, the major environmental form of technetium, is a negatively charged, tetrahedral anion. ${ }^{5}$ The low charge of $\mathrm{TcO}_{4}{ }^{-}$that makes it mobile in the environment, also makes it difficult to detect since it does not bind strongly to most
reagents. A pertechnetate sensor would require strong and selective binding (i.e., minimal or no competition from environmental anions such as chloride, nitrate, phosphate, sulfate, and humic acid) and a signal indicating its binding.

Fluorescent sensing involves the emission of light on binding by the analyte, ${ }^{9}$ and is popular due to its high sensitivity and selectivity. ${ }^{10}$ There are many advantages to using a fluorescent or luminescent molecule for sensing: high sensitivity, high selectivity, short response times ( $<10^{-9} \mathrm{~s}$ ), sampling not needed, nondestructiveness, and processes can be studied in real time. ${ }^{11}$ Modifying functional groups on the fluor can change the fluorescence spectrum observed. Electron-donating substituents cause a shift in the absorption and fluorescence spectrum in addition to increasing the molar absorption coefficient. ${ }^{10}$ The spectra of fluors with electron-donating substituents are often broad and structureless in comparison with the parent aromatic hydrocarbon. ${ }^{10}$ The ability to modify spectra with substituents can be advantageous when designing a specific fluorescent sensor.

Since ${ }^{99} \mathrm{Tc}$ is a beta emitter, radiometric sensing via scintillation counting is one method for generating a signal when $\mathrm{TcO}_{4}{ }^{-}$is bound to the sensor. Each time a $\beta^{-}$particle is emitted, the energy is transferred to a scintillator (or fluor), which then emits light. Scintillation is a term applied to fluorescence emission when it is generated by a radionuclide transferring energy to the fluor. In fluorescence detection, binding of the anion will result in a modification of the original fluorescence signal (i.e., it will fluoresce in the presence of the anion but not in its absence; the wavelength of the fluorescence peak will shift; etc.). In scintillation detection, the presence of a $\beta^{-}$emitting
radionuclide excites the fluor to generate the signal of light, which is then collected and used to count the radionuclide present in the sample.

### 1.5 Current methods of detection for technetium-99

Environmental samples often have small, although possibly toxic, quantities of the element being measured. Samples must often be collected and sent to a laboratory for any necessary separations, sample preparation, and finally analysis. Preconcentration is often a required step, complicating and increasing the time required to analyze each sample. Many conventional methods of detecting species such as heavy metals often require expensive instrumentation such as atomic absorption, inductively coupled plasma, and fluorimetry. ${ }^{12}$ Radionuclides can often be detected based on what is emitted from the nucleus, however different instrumentation is required for each type of emission ( $\gamma$ vs. $\beta^{-}$). Instrumentation is often expensive and usually requires a trained operator. Thus, analyzing environmental samples from a large site or a large number of sites can be time consuming, costly, and labor intensive. There is a need for portable, fast, and low-cost analysis methods for a variety of different environmental contaminants including ${ }^{99} \mathrm{Tc}$.

Technetium-99 is very mobile in the environment, is present as $\mathrm{TcO}_{4}^{-}$, and is present with a wide variety of other anions. Technetium-99 is a pure $\beta^{-}$emitter with a long half-life. For detection, ${ }^{99} \mathrm{Tc}$ must be separated from other interferences (both radioactive and anionic), preconcentrated, and detected. Current methods for measuring ${ }^{99} \mathrm{Tc}$ include sequential injection analysis ${ }^{13-15}$, spectroelectrochemical detection ${ }^{16}$, inductively coupled plasma mass spectrometry (ICP-MS) ${ }^{17,18}$, absorptive stripping voltammetry ${ }^{19}$, and liquid scintillation counting (LSC) ${ }^{20}$ following preconcentration.

The technique of sequential injection analysis was applied by Egorov et. al to preconcentrate and measure ${ }^{99} \mathrm{Tc} .{ }^{13-15}$ This method uses an anion-exchange extractant coated onto a polymeric resin to selectively bind $\mathrm{TcO}_{4}{ }^{-}$in order to preconcentrate it prior to measurement. The ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$is measured in situ by scintillation detection through a primary fluor (usually PPO-2,5-diphenyloxazole) and a secondary fluor (usually bis-MSB-1,4-bis(2-methylstyryl)benzene) that were also coated onto the polymeric resin. Using Aliquat-336 (tricaprylylmethylammonium chloride), ${ }^{14}$ a long-chain quaternary ammonium ion extractant, and solutions of dilute acid ( $0.01-0.02 \mathrm{M} \mathrm{HNO}_{3}$ ), the sensor was able to selectively measure ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$in the presence of ${ }^{90} \mathrm{Sr},{ }^{238} \mathrm{U},{ }^{239} \mathrm{Pu}$, and ${ }^{241} \mathrm{Am}$. The detection efficiency for ${ }^{99} \mathrm{TcO}_{4}{ }^{-}\left(\beta^{-}\right.$particle) was reported to be $44-47 \pm 3 \%$ (depending on the calibration method used) with a detection limit of $3 \mathrm{dpm} / \mathrm{mL}$ in a 30minute count time. The sensor developed preconcentrated and measured the amount of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$present, however the samples had to be acidic (which most environmental and tank wastes are not, thus requiring pretreatment). There was no analysis of the selectivity for $\mathrm{TcO}_{4}{ }^{-}$over other common anions such as chloride, nitrate, phosphate, etc., present in both the environment and nuclear wastes in high concentrations, and chemoluminescence problems with the fluor were reported. Using AG-4x4, a dimethylaminomethyl ammonium functional weakly basic anion exchange resin, Egorov et al. ${ }^{15}$ were able to sufficiently preconcentrate $\mathrm{TcO}_{4}{ }^{-}$under slightly acidic or slightly basic conditions. The AG- $4 \times 4$ resin has a low selectivity for $\mathrm{TcO}_{4}{ }^{-}$and was not compared to other environmentally relevant anions. The detection efficiency for ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$( $\beta^{-}$particle) was reported as $22 \pm 2 \%$ with a detection limit of $6.85 \mathrm{~Bq} / \mathrm{L}$ in a 10 minute count time. Sequential injection analysis has the benefit of reducing the exposure to workers and
reducing secondary wastes such as gloves, vials, etc. Both Aliquat- 336 and AG- $4 \times 4$ can be regenerated for continued use.

In spectroelectrochemical sensing, ${ }^{16}$ the analyte is taken up selectively, electrolyzed selectively, and partitioned into a film where it is then selectively monitored spectroscopically. This process has been shown to work with $\left[\operatorname{Re}^{I}(\mathrm{DMPE})_{3}\right]^{+}{ }^{16}$ a nonradioactive analogue to $\left[{ }^{99 m} \mathrm{Tc}{ }^{\mathrm{I}}(\mathrm{DMPE})_{3}\right]^{+}$, where DMPE $=1,2-$ bis(dimethylphosphino)ethane. The goal was to develop technetium myocardial perfusion imaging agents.

$$
\left[\operatorname{Re}^{\mathrm{I}}(\mathrm{DMPE})_{3}\right]^{+} \rightarrow\left[\operatorname{Re}^{\mathrm{II}}(\mathrm{DMPE})_{3}\right]^{2+}+\mathrm{e}^{-}
$$

In order to sense $\left[\operatorname{Re}{ }^{\mathrm{II}}(\mathrm{DMPE})_{3}\right]^{2+}$, the complex must partition into the coating, undergo a one-electron electrochemical oxidation, and absorb visible light. This discriminates against most, if not all, possible interferents.

Inductively coupled plasma mass spectrometry (ICP-MS) ${ }^{17,18}$ can measure ${ }^{99} \mathrm{Tc}$ with high sensitivity from soil and plant samples. This method has the benefit that common environmental anions do not interfere with the measurement. The only intereferences of concern would be at mass 99; Tagami et. al ${ }^{17}$ found that ${ }^{98} \mathrm{MoH}$ was not an interferent in their samples. However, due to the low concentration of ${ }^{99} \mathrm{Tc}$ in the environment, all the samples must undergo significant preconcentration, resulting in additional waste. Following preconcentration, the sample must have $<300 \mathrm{ppm}$ of total element concentration for the operation of the instrument. ${ }^{17}$ A major drawback to this method is the high cost of the instrument itself.

Adsorption stripping voltammetry can be used to measure $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{Tc}(\mathrm{IV})$ with a detection limit of $5 \times 10^{-11} \mathrm{~g} \mathrm{Tc} / \mathrm{mL} .{ }^{19}$ This process relies on optimum amounts of
thiocyanate, and the sensitivity was reduced considerably in the presence of larger quantities of anions like chloride and sulfate. This makes it unsuitable for analysis of large quantities of environmental samples.

Liquid scintillation is a radiometric method that can be used as a very accurate measurement of ${ }^{99} \mathrm{Tc}$. However, in order to avoid very long count times, the sample must be significantly preconcentrated by some other method. The addition of water and some organic solvents such as chloroform and acetonitrile result in quenching. LSC has been reported using solvent extraction to preconcentrate the ${ }^{99} \mathrm{Tc}$ activity, with cyclohexanone as the extractant. ${ }^{20}$ This method uses $1 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ with $100 \%$ cyclohexanone and shows $>98 \%$ separation from ${ }^{90} \mathrm{Sr},{ }^{137} \mathrm{Cs}, \mathrm{U}, \mathrm{Np}, \mathrm{Pu}, \mathrm{Am}, \mathrm{Ru}, \mathrm{I}$, and rare earth elements. This method has the drawback that the samples must be significantly acidified and large amounts of mixed wastes are generated. The selectivity in the presence of other anions such as chloride, nitrate, etc. was not reported.

Ion-exchange chromatography is a separation method that can be applied to anions or cations. It has been used for the separation of $\mathrm{TcO}_{4}{ }^{-}$in lab scale separations or as part of methods like sequential injection analysis, discussed above. Resins, often polystyrene or ethylvinylbenzene, are coated with or co-polymerized with ion-exchange groups. ${ }^{21}$ For anions, quaternary ammonium groups provide the positive charge required; and for cations, sulfonate, carboxyl, or phosphonate groups provide the negative charge required. A mobile phase containing multiple ions to be separated is introduced to the column; ion-exchange processes occur between the mobile phase and the ion-exchange functional groups bonded to the support material. The ion-exchange resins carry functional groups with a fixed charge and counter ions that are located in the vicinity of
the functional groups to achieve electrical neutrality. ${ }^{21}$ A solute ion replaces the counter ion and is temporarily retained by the fixed charge. Separation of multiple ions is determined by the different affinities toward the stationary phase. If a solution of $\mathrm{TcO}_{4}{ }^{-}$ and $\mathrm{NO}_{3}{ }^{-}$are introduced to a quaternary ammonium resin, two competing equilibria result. ${ }^{21}$

$$
\begin{gathered}
\text { Resin- } \mathrm{NR}_{3}{ }^{+} \mathrm{Cl}^{-}+\mathrm{TcO}_{4}^{-}
\end{gathered}{\mathrm{Resin}-\mathrm{NR}_{3}{ }^{+} \mathrm{TcO}_{4}^{-}+\mathrm{Cl}^{-}}^{\text {Resin}-\mathrm{NR}_{3}{ }^{+} \mathrm{Cl}^{-}+\mathrm{NO}_{3}^{-}} \leftrightarrow \text { Resin- } \mathrm{NR}_{3}{ }^{+} \mathrm{NO}_{3}{ }^{-}+\mathrm{Cl}^{-}-1 .
$$

Small and/or highly charged anions have large hydration energies which increases their effective size/charge ratio. This increase in size/charge makes it more difficult for these anions to approach the positively charged ammonium groups as the number of alkyl groups in the chain increases. The larger the alkyl chain, the more selective the anionexchanger will be for low hydration energy anions like $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{I}^{-}$.

Several key problems exist with using anion-exchangers, such as Aliquat-336 and AG-4x4. The anion-exchanger does not preconcentrate the anions present. The sample must be sufficiently preconcentrated before separation. Using large elution volumes or large sample volumes will cause loss of separation as bleeding of bands of anions occurs. Ion-exchange columns also do not have a sensing method; conductivity and UV-Vis detection are the two most common methods of determining when, how much, and which anion has eluted. ${ }^{21}$ UV-Vis cannot be used to detect $\mathrm{TcO}_{4}{ }^{-}$and conductivity measurements when other anions are present in significantly higher concentration makes analysis difficult. Anion-exchange can be used to separate $\mathrm{TcO}_{4}{ }^{-}$from other anions but
does not provide a solution to the preconcentration and analysis problems seen in other methods to quantify $\mathrm{TcO}_{4}{ }^{-}$.

### 1.6 Phosphinimines

Phosphinimines of the type $\mathrm{R}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (sometimes referred to as azaphosphanes) have been shown to form kinetically inert compounds with early transition metals. ${ }^{22,23}$ Metal halides react with $\mathrm{R}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ to eliminate $\mathrm{Me}_{3} \mathrm{SiX}$ (where $\mathrm{X}=$ halide), while metal oxides react through migration of $\mathrm{Me}_{3} \mathrm{Si}$ onto the oxygen of the metal center. ${ }^{23} \mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ has been shown to form $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{N}-\mathrm{ReO}_{3}$ or $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$depending on the reaction conditions. ${ }^{23}$ The corresponding $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{N}-\mathrm{TcO}_{3}$ and $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$have also been produced. ${ }^{22}$ The neutral $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{N}-$ $\mathrm{MO}_{3}(\mathrm{M}=\mathrm{Re}, \mathrm{Tc})$ can be formed on reaction of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ and $\mathrm{NH}_{4} \mathrm{MO}_{4}$ in the absence of water. ${ }^{22,23}$ This neutral compound is of interest for nuclear medicine applications, since ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ and ${ }^{188} \mathrm{Re}$ are used for imaging the body and cancer therapy, respectively. The ion pair $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{MO}_{4}^{-}\right]$can be generated by reaction of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ dissolved in an organic solvent mixed with an aqueous solution of $\mathrm{NH}_{4} \mathrm{MO}_{4}$ or $\mathrm{NaMO}_{4}$ (Scheme 1). ${ }^{22,23}$ Formation of the ion pair may allow for selective separation of $\mathrm{TcO}_{4}^{-}$in the presence of other anions, ${ }^{22}$ and preliminary studies on the selectivity of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ for $\mathrm{TcO}_{4}{ }^{-}$have been reported. ${ }^{24}$ The phosphinimine undergoes a hydrolysis reaction in the presence of water to form the phosphiniminium cation, which forms an ion pair in the presence of an anion (Scheme 1). The phosphiniminium cation is not stable on its own, and if not stabilized by an anion will undergo further hydrolysis to form the phosphine oxide (Scheme 2). The $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$ion pair appears to have considerable stability since Eble et. al ${ }^{22}$
did not observe degradation of the ion pair to free pertechnetate in aqueous solution. The ability to extract $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions could make phosphinimines useful for monitoring or cleanup of environmental contamination and/or nuclear waste separations.

## Scheme 1. Hydrolysis of phosphinimine and formation of ion pair

## Scheme 2. Hydrolysis of phosphiniminium cation to phosphine oxide

### 1.7 Objective

The overall goal of this project is to develop a sensor using phosphinimines that can preconcentrate and measure ${ }^{99} \mathrm{Tc}$ environmental contamination in a fast and efficient manner. Cleanup of nuclear waste for reprocessing and/or cleanup of tank waste may also be possible using phosphinimines. The purpose of this portion of the project is to synthesize several phosphinimines and characterize their stability and selectivity with ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$. The phosphinimine analogs evaluated include $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$. Preliminary studies with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ showed the
phosphiniminium cation to be selective for ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$over other anions. ${ }^{24}$ (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ are previously unreported phosphinimines. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ and (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ include possible reporter groups and $(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ contains a linking moiety for attaching reporter groups or attaching the phosphinimine to a polymer support. The phosphiniminium cations of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ showed selectivity for $\mathrm{TcO}_{4}{ }^{-}$over other anions and form stable complexes. The use of internal and external reporter groups to generate a signal was investigated with these two phosphinimines. The phosphiniminium cations of (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ show selectivity but the phosphiniminium perrhenate complexes show instability in solution.

## CHAPTER 2: SYNTHESIS OF COMPOUNDS

### 2.1 Introduction

The goal of this project is to use phosphinimines, $\mathrm{R}_{3} \mathrm{P}=\mathrm{N}-\mathrm{SiMe}_{3}$, as extractants to preconcentrate $\mathrm{TcO}_{4}{ }^{-}$(the major form of technetium in the environment) ${ }^{5}$ in the presence of other anions for analysis, separation, or cleanup of environmental samples and/or nuclear waste samples. Phosphinimines hydrolyze under acidic and neutral conditions to form the phosphiniminium ion, $\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$. This cation then forms an ion pair with anions to stabilize the charge (Scheme 1). To produce a sensor using phosphinimine extractants, the extractant must bind $\mathrm{TcO}_{4}{ }^{-}$selectively and a reporter must generate a measurable signal. The phosphinimines synthesized include $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$, and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$. The synthesis of the new phosphinimines of the type $\mathrm{R}_{2} \mathrm{R}^{\prime} \mathrm{P}=\mathrm{NSiMe}_{3}$, where $\mathrm{R}=\mathrm{Ph}, \mathrm{R}^{\prime}=9$-anthracenyl, 1-napthyl, $(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4}$ along with their characterization are described.

The crystal structures of $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]^{23}$ and $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]^{22}$ have been reported and are isostructural. Preliminary studies for extraction of the $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$ion pair have been reported and show the phosphinimine to be selective for ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$over other anions. ${ }^{24}$ While the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ shows selectivity for $\mathrm{TcO}_{4}^{-}$, this phosphinimine does not contain a reporter group; an external reporter would be necessary.
(9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) was synthesized to incorporate the anthracene moiety for use as a fluorescent or scintillation reporter. Anthracene is a fluorescent molecule that is also a known scintillator. ${ }^{25}$
(1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ was synthesized to incorporate the napthyl moiety. Napthyl also fluoresces and is a known alpha scintillator. ${ }^{25}$ This molecule was also synthesized for comparison with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2).
(p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8) was synthesized as a precursor molecule. The COOMe is present as a protecting group for COOH . The protecting group can be removed chemically and then reacted further to attach another group to this site. Possible attachment options include a polymer support or a reporting group. Reporting groups could include fluorescent molecules like fluorescein or groups that change color, oxidation state, etc.

The attempted synthesis of (anthracen-9-ylmethyl)diphenylphosphine (10) was performed to produce a phosphinimine that would allow further investigation of the fluorescent and scintillation properties of the phosphinyl anthracene moiety.

The selectivity and extraction behavior of the phosphinimines for $\mathrm{TcO}_{4}{ }^{-}$is reported in Chapter 3: Radiochemistry. The fluorescence and scintillation properties of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) as a possible method of signal generation in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$is reported in Chapter 4: Fluorescence / Scintillation Sensor Design. The extraction of $\mathrm{TcO}_{4}{ }^{-}$using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) in the presence of external scintillators as a method of signal generation is reported in Chapter 4: Fluorescence / Scintillation Sensor Design.

### 2.2 Experimental

General Considerations. Caution! ${ }^{99}$ Tc emits a $0.292 \mathrm{MeV} \beta^{-}$with a half-life of $2.15 \times 10^{5}$ years. Although common laboratory glassware provides adequate shielding for ${ }^{99}$ Tc , standard radiation safety procedures must be used at all times.

Materials. ${ }^{99} \mathrm{Tc}$ was obtained from Oak Ridge National Laboratory as ammonium pertechnetate. Ammonium perrhenate was purchased from Strem. Azidotrimethylsilane was purchased from either Aldrich or Acros. (9-anthracenyl)diphenylphosphane ${ }^{26}\left(\mathrm{PPh}_{2}\right.$ anthracenyl), naphthalen-1-yldiphenylphosphane ${ }^{27}\left(\mathrm{PPh}_{2}\right.$ naphthyl), and methyl 4-(diphenylphosphino)benzoate ${ }^{28}$ $\left(\mathrm{PPh}_{2} \mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{p}-\mathrm{COOMe})\right)$ were prepared according to literature procedures. Silica gel was obtained from J. T. Baker, heated to $110^{\circ} \mathrm{C}$ overnight in an oven and used without further purification. Only doubly distilled water was used.

Unless noted, all common laboratory chemicals were of reagent grade or better. Solvents used for nonaqueous syntheses were purchased as anhydrous Sure Seal solvents from Aldrich. Solvents included tetrahydrofuran (THF), toluene and dimethylsulfoxide (DMSO). ${ }^{1} \mathrm{H}-,{ }^{31} \mathrm{P}$ - and ${ }^{99} \mathrm{Tc}$ - NMR spectra were recorded on a Bruker 250 or 500 MHz instrument at $25^{\circ} \mathrm{C}$ in deuterated solvents purchased from Cambridge Isotope Laboratories. ${ }^{1} \mathrm{H}$ chemical shifts are reported in ppm relative to the ${ }^{1} \mathrm{H}$ impurity in that solvent and ${ }^{31} \mathrm{P}$ chemical shifts are reported in ppm relative to an external $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ standard. ${ }^{99} \mathrm{Tc}$ chemical shifts were reported relative to $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ set to zero in water; $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ in acetonitrile was observed at 13.61 ppm . ESI and APCI mass spectra were recorded on a Finnigan TSQ7000 in acetonitrile. Elemental analysis of $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) was performed by Quantitative Technologies

Inc. (QTI, Whitehouse, NJ). Elemental analysis of $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$ (4) was performed by Atlantic Microlab, Inc. (Norcross, GA). Thin layer chromatography (TLC) on $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4) was performed on a BioScan System 200 Imaging Scanner. The reactions to synthesize $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1), (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6), (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8)$ and $\left((9\right.$-anthracenyl $\left.)-\mathrm{CH}_{2}\right) \mathrm{Ph}_{2} \mathrm{P}(\mathbf{1 0})$ were carried out on a Schlenk-line under $\mathrm{N}_{2}$ using general airfree techniques.
$\mathbf{P h}_{3} \mathbf{P}=\mathbf{N S i M e}_{3} \mathbf{( 1 ) .} \mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ was prepared according to a modification of the literature procedure. ${ }^{23,29}$ Triphenylphosphine (Acros) was heated to $125^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ with three to six equivalents $\mathrm{N}_{3} \mathrm{SiMe}_{3}$ (Acros or Aldrich) in a dry and $\mathrm{N}_{2}$ filled roundbottom flask for 5 hours using standard airfree Schlenk-line techniques. The excess azide was removed by vacuum distillation and the remaining solid was crystallized from acetonitrile at $-20^{\circ} \mathrm{C}$ to yield pure $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ which was then stored in a desiccator.
(9-anthracenyl) $\mathbf{P h}_{\mathbf{2}} \mathbf{P}=\mathbf{N S i M e}_{3}$ (2). Azidotrimethylsilane ( $11.1 \mathrm{~mL}, 80.8 \mathrm{mmol}$ ) was added to $\mathrm{PPh}_{2}$ anthracenyl $(9.8 \mathrm{~g}, 27.0 \mathrm{mmol})$ dissolved in 200 mL of toluene in a dry and $\mathrm{N}_{2}$ filled round-bottom flask. The solution was refluxed under $\mathrm{N}_{2}$ at $110^{\circ} \mathrm{C}$ for 8 days yielding (2). An additional 5 mL of azidotrimethylsilane was added each day. The excess azide was removed by vacuum distillation to yield pure (2) which was then stored in a desiccator. Yield: $10.2 \mathrm{~g}(83.9 \%)$ isolated. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 6.84-8.46$ ( $\mathrm{m}, 20 \mathrm{H}, \mathrm{Ar}), 0.26\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{SiMe}_{3}\right) .{ }^{31} \mathrm{P}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm}-6.86 . \operatorname{MS}$ APCI $(\mathrm{m} / \mathrm{z})$ 450.23, calc'd $449.17 \mathrm{C}_{29} \mathrm{H}_{28} \mathrm{NPSi}$.
[(9-anthracenyl) $\left.\mathbf{P h}_{2} \mathbf{P}=\mathbf{N H}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right.$] (3). Method 1. $\mathrm{NH}_{4} \mathrm{ReO}_{4}(0.240 \mathrm{~g}, 0.896$ $\mathrm{mmol})$ dissolved in the minimum volume water $(4 \mathrm{~mL})$ was added dropwise to a solution
of (2) $(0.400 \mathrm{~g}, 0.890 \mathrm{mmol})$ dissolved in the minimum volume of acetonitrile ( 35 mL ), under $\mathrm{N}_{2}$, while stirring for 5-10 minutes. The reaction mixture was stirred for 2-4 hours. The solvent was removed and the solid was washed with toluene to remove unreacted (2) and phosphine oxide. X-ray quality crystals were obtained from acetonitrile/water (89/11 $\%$ ratio) at $-20^{\circ} \mathrm{C}$ and then melting the ice leaving the crystals. Crystals for all other analyses were obtained from the slow evaporation of acetonitrile. Yield $0.45 \mathrm{~g}(80 \%)$ isolated. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 7.28-9.16(\mathrm{~m}, 20 \mathrm{H}, \mathrm{Ar}), 2.20\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NH}_{2}\right)$. ${ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right)$ : $\delta$ ppm 34.55. Anal. for $\mathrm{C}_{26} \mathrm{H}_{21} \mathrm{NO}_{4} \mathrm{Re}$ Found (Calcd): C, 50.05 (49.68)\%; H, 3.05 (3.37)\%; N, 2.41 (2.23)\%. MS +ESI ( $\mathrm{m} / \mathrm{z}$ ) 378.12, calc'd $378.14\left(\mathrm{C}_{26} \mathrm{H}_{21} \mathrm{NP}^{+}\right) ;$-ESI ( $\mathrm{m} / \mathrm{z}$ ) 248.89, calc'd $248.93\left({ }^{185} \mathrm{ReO}_{4}{ }^{-}\right)$, 250.88 , calc'd 250.94 $\left({ }^{187} \mathrm{ReO}_{4}^{-}\right)$.

Method 2 - Optimization of yield for (3). $\mathrm{NH}_{4} \mathrm{ReO}_{4}(0.1230 \mathrm{~g}, 0.4590 \mathrm{mmol})$ dissolved in 5 mL of 0.15 M HCl was added dropwise to a solution of (2) ( 0.2000 g , 0.4453 mmol ) dissolved in 30 mL of acetonitrile in a round-bottom flask, under $\mathrm{N}_{2}$, while stirring for 5-10 minutes. The reaction mixture was stirred for 1 hour. The solvent was removed by vacuum. The product was not isolated since this was an optimization of the previous procedure. The yield was quantitative by ${ }^{31} \mathrm{P}$ NMR. ${ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right)$ : $\delta \mathrm{ppm} 33.55 . \mathrm{MS}+\mathrm{ESI}(\mathrm{m} / \mathrm{z}) 378.02$, calc'd $378.14\left(\mathrm{C}_{26} \mathrm{H}_{21} \mathrm{NP}^{+}\right)$; -ESI $(\mathrm{m} / \mathrm{z})$ 248.77, calc'd $248.93\left({ }^{185} \mathrm{ReO}_{4}{ }^{-}\right), 250.77$, calc'd $250.94\left({ }^{187} \mathrm{ReO}_{4}{ }^{-}\right)$.

## [(9-anthracenyl) $\left.\mathbf{P h}_{2} \mathbf{P}=\mathbf{N H}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4). $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}(0.030 \mathrm{~g}, 0.166 \mathrm{mmol})$

 dissolved in 0.83 mL of water was added dropwise to a solution of (2) $(0.0740 \mathrm{~g}, 0.165$ mmol ) dissolved in $10-15 \mathrm{~mL}$ of acetonitrile, while stirring under air. The reaction was stirred for approximately 1 hour. X-ray quality crystals were obtained from slowevaporation of acetonitrile. The yield was determined using aluminum backed silica gel developed in saline and counted on the BioScan 200 Imaging instrument. The product remained at the origin $\left(\mathrm{R}_{\mathrm{f}}=0\right)$ while the ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$traveled with the solvent front $\left(\mathrm{R}_{\mathrm{f}}=1\right)$. Yield: 48.2 (\%). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 7.36-9.14(\mathrm{~m}, 20 \mathrm{H}, \mathrm{Ar}), 2.13(\mathrm{~s}, 2 \mathrm{H}$, $\left.\mathrm{NH}_{2}\right) .{ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 34.68 .{ }^{99} \mathrm{Tc}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm}$ 14.66. Anal. for $\mathrm{C}_{26} \mathrm{H}_{21} \mathrm{NO}_{4} \mathrm{Tc}$ Found (Calcd): C, 57.55 (57.69)\%; H, 4.07 (3.91)\%; N, 2.78 (2.59)\%.
[(9-anthracenyl) $\mathbf{P h}_{2} \mathbf{P}=\mathbf{N H}_{2}{ }^{+}$][benzoate] (5). Sodium benzoate ( $0.06 \mathrm{~g}, 0.49$ $\mathrm{mmol})$ dissolved in 5 mL of water $(\mathrm{pH}=6)$ was added dropwise to a solution of (2) (0.20 $\mathrm{g}, 0.45 \mathrm{mmol}$ ) dissolved in 30 mL of acetonitrile in a round-bottom flask, under $\mathrm{N}_{2}$ while stirring. The reaction was stirred for 3.5 hours. Solvent was removed, the solid was washed with toluene to remove any phosphine oxide, and the final product was taken up in acetonitrile. X-ray quality crystals were grown from $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ but were found to be anthraquinone. ${ }^{31} \mathrm{P}$ NMR of reaction $\left(\mathrm{CH}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm}$ 28.39. MS $+\mathrm{ESI}(\mathrm{m} / \mathrm{z})$ 377.94, calc'd $378.14\left(\mathrm{C}_{26} \mathrm{H}_{21} \mathrm{NP}^{+}\right) .{ }^{31} \mathrm{P}$ NMR of mother liquor $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm}$ 31.47, 23.59, many signals between 16.31-41.98.
(1-napthyl) $\mathbf{P h}_{2} \mathbf{P}=\mathbf{N S i M e}_{3}$ (6). Azidotrimethylsilane ( $8 \mathrm{~mL}, 18.0 \mathrm{mmol}$ ) was added to $\mathrm{PPh}_{2}$ napthyl $(5.63 \mathrm{~g}, 58.2 \mathrm{mmol})$ dissolved in 60 mL of toluene in a dry and $\mathrm{N}_{2}$ filled round-bottom flask. The solution was refluxed under $\mathrm{N}_{2}$ at $110^{\circ} \mathrm{C}$ for 2 days yielding (6). An additional 2 mL of azidotrimethylsilane was added on the second day. The excess azide was removed by vacuum distillation to yield pure (6) which was then stored in a dessicator. Yield: $4.50 \mathrm{~g}(62.4 \%)$ isolated. ${ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm}$

(p-COOMe) $\mathbf{C}_{6} \mathbf{H}_{4} \mathbf{P h}_{2} \mathbf{P}=$ NSiMe $_{3}$ (8). Azidotrimethylsilane ( 2 mL , 14.6 mmol ) was added to $\mathrm{PPh}_{2} \mathrm{C}_{6} \mathrm{H}_{5}(\mathrm{p}-\mathrm{COOMe})(0.23 \mathrm{~g}, 0.718 \mathrm{mmol})$ in a dry and $\mathrm{N}_{2}$ filled roundbottom flask. The solution was refluxed under $\mathrm{N}_{2}$ at $110^{\circ} \mathrm{C}$ overnight yielding (8). The excess azide was removed by vacuum distillation to yield pure (8) which was then stored in a dessicator. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 7.53-8.12(\mathrm{~m}, 26 \mathrm{H}, \mathrm{Ar}),-0.064(\mathrm{~s}, 9 \mathrm{H}$, $\left.\mathrm{SiMe}_{3}\right), 3.95\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{31} \mathrm{P} \operatorname{NMR}\left(\mathrm{CD}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 0.22$. MS APCI ( $\mathrm{m} / \mathrm{z}$ ) 408.04, calc'd $407.15 \mathrm{C}_{23} \mathrm{H}_{26} \mathrm{NO}_{2} \mathrm{PSi}$.
[( $\left.\mathbf{p}-\mathbf{C O O M e}) \mathbf{C}_{6} \mathbf{H}_{4} \mathbf{P h}_{\mathbf{2}} \mathbf{P}=\mathbf{N H}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(9). $\quad \mathrm{NH}_{4} \mathrm{ReO}_{4}(0.0940 \mathrm{~g}, 0.3504$
$\mathrm{mmol})$ dissolved in 4 mL of water was added dropwise to a solution of (8) ( 0.1510 g , 0.3705 mmol ) dissolved in 4 mL of dichloromethane in a round-bottom flask, under $\mathrm{N}_{2}$, while stirring. The reaction was stirred vigorously for 30 minutes. The reaction was centrifuged for 10 minutes. The dichloromethane was removed by vacuum distillation
yielding (9). MS +ESI ( $\mathrm{m} / \mathrm{z}$ ) 335.93, calc'd $336.11\left(\mathrm{C}_{20} \mathrm{H}_{19} \mathrm{NO}_{2} \mathrm{P}^{+}\right)$; - ESI ( $\mathrm{m} / \mathrm{z}$ ) 248.76, calc'd $248.93\left({ }^{185} \mathrm{ReO}_{4}{ }^{-}\right), 250.74$, calc'd $250.94\left({ }^{187} \mathrm{ReO}_{4}{ }^{-}\right)$.

Attempted synthesis of ((9-anthracenyl)- $\left.\mathrm{CH}_{2}\right) \mathbf{P h} \mathbf{2}_{2} \mathbf{P}$ (10). Method 1. Lithium diphenylphosphide ( 0.5 M in THF, $5 \mathrm{~mL}, 2.5 \mathrm{mmol}$ ) was cooled to $-70^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ in a dry ice/ethanol bath. 9-(chloromethyl)anthracene ( $0.56 \mathrm{~g}, 2.47 \mathrm{mmol}$ ) in 10 mL of anhydrous THF was added dropwise while stirring. The reaction was stirred at $-70^{\circ} \mathrm{C}$ for 1 hour, allowed to warm to room temperature over 1 hour, and finally heated to $80^{\circ} \mathrm{C}$ overnight. Heat was then removed and as the reaction cooled a precipitate formed. Reaction at 30 minutes: ${ }^{31} \mathrm{P}$ NMR (THF, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm}-9.41,-15.49,-39.99$. Reaction at 1 hour: no change. Reaction at room temperature: ${ }^{31} \mathrm{P}$ NMR (THF, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm}-9.24$, -15.44. Reaction after heating 2 hours: ${ }^{31} \mathrm{P}$ NMR (THF, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm}-9.43,-15.42$, 51.61. Reaction after heating overnight: ${ }^{31} \mathrm{P}$ NMR (THF, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm} 36.11,-9.41,-$ 15.49. Solution above precipitate: ${ }^{31} \mathrm{P}$ NMR (THF, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm} 34.58,33.32,32.83$, 32.50, 32.35, 31.81, 29.96, 28.77, 27.18, -10.94, -16.99. Precipitate: ${ }^{31}$ P NMR (THF, $\left.25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 31.75,-11.88,-17.09$.

Method 2. Lithium diphenylphosphide ( 0.5 M in THF, $5 \mathrm{~mL}, 2.5 \mathrm{mmol}$ ) was cooled to $-70^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ in a dry ice/ethanol bath. 9-(chloromethyl)anthracene ( 0.56 g , 2.47 mmol ) in 5 mL of anhydrous THF was added dropwise while stirring. The reaction was stirred at $-70^{\circ} \mathrm{C}$ for 30 minutes and then refluxed for 21 hours. The color of the reaction was blood red for 9 hours after beginning of reflux. At 9 hours the solution became brown red with a brown flocculent precipitate and after 21 hours the solution was a yellow brown with a brown flocculent precipitate. ${ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CH}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right)$ : $\delta \mathrm{ppm}$
35.68, $-9.37,-15.34,-51.43$ (reaction mixture). MS +ESI $(\mathrm{m} / \mathrm{z})$ no peaks of possible product, oxide, or starting materials.

Method 3. n - $\mathrm{BuLi}\left(1.4 \mathrm{~mL}\right.$ of 1.6 M in hexanes, 2.24 mmol ) was cooled to $-70^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$ in a dry ice/ethanol bath and diluted with 5 mL of anhydrous THF. 9(chloromethyl)anthracene $(0.5005 \mathrm{~g}, 2.21 \mathrm{mmol})$ in 10 mL of anhydrous THF was added dropwise while stirring. The reaction was allowed to stir for 30 minutes.

Chlorodiphenylphosphide ( $0.4 \mathrm{~mL}, 2.23 \mathrm{mmol}$ ) in 6 mL of anhydrous THF was added dropwise while stirring. The reaction was allowed to stir for 1 hour and then the ${ }^{31} \mathrm{P}$ NMR spectrum was acquired. ${ }^{31} \mathrm{P}$ NMR $\left(\mathrm{CH}_{3} \mathrm{CN}, 25^{\circ} \mathrm{C}\right): \delta \mathrm{ppm} 112.39,83.06,8$ peaks between 42.17-13.63, -21.98, -22.82.

Method 4. Diphenylphosphine ( $0.45 \mathrm{~mL}, 2.59 \mathrm{mmol}$ ) was added, under $\mathrm{N}_{2}$, to 10 mL of stirring anhydrous DMSO. Potassium hydroxide ( $0.163 \mathrm{~g}, 2.9 \mathrm{mmol}$ ) in 1.43 mL of water was added dropwise while stirring. The color changed from clear colorless to a clear orange. After 15 minutes of stirring, 9-(chloromethyl)anthracene ( $0.5607 \mathrm{~g}, 2.47$ mmol ) in 10 mL of DMSO was added dropwise. The color changed to bright yellow. The reaction was heated to $135^{\circ} \mathrm{C}$ over 1 hr and heated at $135^{\circ} \mathrm{C}$ for an additional hour. The oil bath was removed and 50 mL of distilled water was added to the reaction. A precipitate immediately formed. This was stirred in an ice bath for 1 hour. An additional 20 mL of distilled water was added and the reaction was stirred for 1 hour. The solution was filtered and a yellow solid collected. After heating: ${ }^{31} \mathrm{P}$ NMR (DMSO, $25^{\circ} \mathrm{C}$ ): $\delta$ ppm 28.78, 24.86, 20.72, -8.29, -39.68. Final solid: ${ }^{31} \mathrm{P}$ NMR (DMSO, $25^{\circ} \mathrm{C}$ ): $\delta \mathrm{ppm}$ 28.03 24.87. MS +ESI $(\mathrm{m} / \mathrm{z}) 415.01$, calc'd $463.19 \mathrm{C}_{30} \mathrm{H}_{30} \mathrm{NPSi}$, calc'd 415.12 $\mathrm{C}_{27} \mathrm{H}_{21} \mathrm{NaOP}$.

X-ray Structure Determinations and Refinements for (3) and (4). Intensity data were obtained at $-100^{\circ} \mathrm{C}$ on a Bruker SMART CCD Area Detector system using the $\omega$ scan technique with $\mathrm{Mo} \mathrm{K} \alpha$ radiation from a graphite monochromator. Intensities were corrected for Lorentz and polarization effects. Equivalent reflections were merged, and absorption corrections were made using the multi-scan method. The structure was solved by direct methods with full-matrix least-squares refinement, using the SHELX package. ${ }^{30,31}$ All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were placed at calculated positions and included in the refinement using a riding model, with fixed isotropic $U$. The final difference map contained no features of chemical significance. Selected bond distances and bond angles of $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}^{-}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$(4) are given in Table 4. Space group, lattice parameters and other relevant information for $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4) along with the data are given in Appendix 1.

### 2.3 Results and Discussion

Phosphinimines, $\mathrm{R}_{3} \mathrm{P}=\mathrm{N}-\mathrm{SiMe}_{3}$, were synthesized as potential extractants for preconcentrating $\mathrm{TcO}_{4}^{-}$in the presence of other anions for analysis, separation, or cleanup. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) contains the anthracene moiety, which is a known scintillator, ${ }^{25}$ while (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ incorporates the napthyl moiety, which has been reported as an alpha scintillator. ${ }^{25}(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8) contains a protected linker arm to potentially append reporter groups or attach the phosphinimine to a polymer.

Synthesis. To produce (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) or
(1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6), \mathrm{PPh}_{2}$ anthracenyl or $\mathrm{PPh}_{2}$ napthyl were refluxed in toluene with $\mathrm{N}_{3} \mathrm{SiMe}_{3}$ (Schemes 3, 4, 5 and Table 2). To produce (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8), \mathrm{PPh}_{2} \mathrm{C}_{6} \mathrm{H}_{4}(\mathrm{p}-\mathrm{COOMe})$ and $\mathrm{N}_{3} \mathrm{SiMe}_{3}$ were refluxed under $\mathrm{N}_{2}$ (Scheme 6). The reactions were monitored by ${ }^{31} \mathrm{P}$ NMR to determine the completion time as the starting material peak decreased and then disappeared and the product peak appeared. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) is a dark red-brown solid, (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ is a light tan or off white solid, and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8)$ is a dark brown oil.

Scheme 3: General synthesis of phosphinimines

Scheme 4. Synthesis of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2)

Scheme 5. Synthesis of (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6)

(6)

Scheme 6. Synthesis of (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8)

Table 2: Phosphinimines synthesized
Compound 8 R, R' $\quad$ Phenyl

Table 3: Phosphiniminium permetallates synthesized

| Compound | Phosphinimine | Anion | Product | Color of Crystal |
| :---: | :---: | :---: | :---: | :---: |
| 3 | 2 | $\mathrm{ReO}_{4}{ }^{-}$ |  | Yellow |
| 4 | 2 | $\mathrm{TcO}_{4}{ }^{-}$ |  | Yellowbrown |
| 5 | 2 | Sodium benzoate |  | N/A |
| 7 | 6 | $\mathrm{ReO}_{4}{ }^{-}$ |  | N/A |
| 9 | 8 | $\mathrm{ReO}_{4}{ }^{-}$ |  | N/A |

Reaction of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ yielded [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4), respectively (Scheme 1, Table 3). Crystals for $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4) were grown by slow evaporation from acetonitrile. Unreacted $\mathrm{NH}_{4} \mathrm{TcO}_{4}$ co-crystallized as colorless crystals. While (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)$ is mildly moisture sensitive (i.e., hydrolyzes to the phosphine oxide upon exposure to water over time) and should be stored in a desiccator, $\left[\left(9\right.\right.$-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4) do not degrade as solids or in solution. Reaction of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with sodium benzoate yielded [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\right.$benzoate] (5). Over a week in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, X-ray quality crystals were grown of anthraquinone. The crystals showed no ${ }^{31} \mathrm{P}$ NMR signal while the mother liquor showed a variety of products from the rearrangement.

Reaction of (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ yielded [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7) (Scheme 1, Table 3). Crystals of [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7) where not grown since (7) degrades in solution. Solutions of [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7) in solvents such as acetonitrile, dichloromethane, or the reaction mixture of dichloromethane/water led to decomposition after 1-3 hours.

Reaction of $(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ yielded $\left[(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(9) (Scheme 1, Table 3). The yield for (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ was not determined since the product is a thick oil that hydrolyzed quickly in air. $\left[(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right](9)$ is not stable in
solution, decomposing in minutes, so no crystals were grown or NMR spectrum recorded. The product was identified by mass spectrometry.

NMR Characterization. The NMR spectrum for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) was taken in benzene, while $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$(4) were run in acetonitrile. From the NMR spectra, it is seen that $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$(4) have almost the same effect on both the ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ nuclei, however this chemical environment is significantly different from (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2). The ${ }^{31} \mathrm{P}$ peak shifted from -6.86 ppm for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) to 34.55 ppm for $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$ (3) and 34.68 ppm for $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4). The same effect is observed in the ${ }^{1} \mathrm{H}$ NMR spectra for the aromatic resonances, which shift from 6.84-8.46 for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) to 7.38-9.17 for [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) and 7.36-9.14 for [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4). The formation of the ion pair does not significantly change the ${ }^{99} \mathrm{Tc}$ NMR chemical shift for [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) since the technetium coordination sphere has not significantly changed; 14.66 ppm for $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) and 13.61 ppm for $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ in acetonitrile. The same trends are observed in the ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectra for (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) and [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$ (7).

X-ray Crystallography. Yellow crystals of [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$ (3) and yellow-brown crystals of $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) were obtained
as described and were stable to air and water during the analysis and for months afterward. Details of the X-ray structure experiments are given in Appendix 1 and the bond lengths and angles of interest are listed in Table 4. Figures 1 and 2 show the ORTEP ${ }^{30,31}$ diagrams of [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4), respectively. The two structures are isostructural and show a strong hydrogen bond between an iminium proton and an oxygen on $\mathrm{MO}_{4}^{-}$in each unit cell. The extended lattice shows that $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[\left(9\right.\right.$-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right](4)$ form dimers, with each $\mathrm{MO}_{4}{ }^{-}$bound to two phosphiniminium ligands and each phosphiniminium hydrogen bonded to two $\mathrm{MO}_{4}{ }^{-}$moieties. The structure is symmetrical, with each unit cell containing only one half of each dimer. The hydrogen bond distances between the iminium proton and the M-O oxygen for perrhenate ( $1.95 \AA$ ) was slightly shorter than for pertechnetate (2.06 $\AA$ ). The M-O bond distances observed for both the perrhenate (1.703-1.728(2) $\AA$ ) and pertechnetate (1.6907-1.7126(16) $\AA$ ) are typical for these species. ${ }^{32}$ The structures for $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}\right]^{22}$ and $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]^{23}$ were previously reported and also showed a strong hydrogen bond between the iminium protons and an oxygen on two different $\mathrm{MO}_{4}{ }^{-}$moieties. Both were reported as dimers with two oxygen groups on each $\mathrm{MO}_{4}{ }^{-}$bound to two iminium protons, one each on two different phosphiniminium cations. $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$was shown to have oxygen-nitrogen bond distances of 2.871 and $2.951 \AA$, M-O distances of $1.690-$ $1.727(7) \AA$, and the hydrogen bond distances were not reported. ${ }^{23}\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$ was shown to have oxygen-nitrogen bond distances of 2.855 and $2.973 \AA$, M-O distances of 1.690-1.708(4) $\AA$, and hydrogen bond distances of $1.89(6)$ and $2.23(6) \AA .^{22}$

Figure 1. ORTEP representation of $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3), with $\mathbf{5 0 \%}$ thermal ellipsoids

Figure 2. ORTEP representation of $\left[(9-a n t h r a c e n y l) \mathbf{P h}_{2} \mathbf{P}=\mathbf{N H}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4), with 50 \% thermal ellipsoids

Table 4. * Denotes hydrogen atoms located on the nitrogen

Attempted Synthesis of ((9-anthracenyl)- $\left.\mathbf{C H}_{2}\right) \mathbf{P h}_{2} \mathbf{P}$ (10). This phosphine was of interest as a comparator to (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)$ since it would allow further investigation of the fluorescence and scintillation properties of the anthracene moiety. All reactions were followed by ${ }^{31} \mathrm{P}$ NMR. The ${ }^{31} \mathrm{P}$ NMR chemical shift for $\mathrm{Ph}_{2} \mathrm{PLi}$ is $\delta \mathrm{ppm}-15.890$ and for $\mathrm{Ph}_{2} \mathrm{PCl}$ is 84.24 .

Method 1 is shown in Scheme 7. A solution of $\mathrm{Ph}_{2} \mathrm{PLi}$ was cooled during the addition of 9-chloromethylanthracene. The major ${ }^{31}$ P NMR peak after the addition and stirring was the $\mathrm{Ph}_{2} \mathrm{PLi}$ starting material. Heating overnight did not produce the desired product as the major product, if at all. Starting material, a variety of oxides, and unidentified materials were generated.

Scheme 7. Attempted Synthesis of ((9-anthracenyl)- $\left.\mathbf{C H}_{2}\right) \mathbf{P h}_{2} \mathbf{P}$ (10) by Method 1 and 2

Method 2 was a modification of Method 1, except the reaction was cooled at $-70^{\circ} \mathrm{C}$ for 30 minutes and then heated to reflux for 21 hours. The reaction was heated to a higher temperature in an attempt to induce the reaction to proceed without producing as many side products as Method 1. The major species at the end of reaction was the starting material of $\mathrm{Ph}_{2} \mathrm{PLi}$ as determined by the -15.493 ppm peak in the ${ }^{31} \mathrm{P}$ NMR. This
method was abandoned after determining by mass spectrometry that none of the peaks in the NMR spectrum belonged to the product.

Method 3 was an attempt to lithiate the methyl on the anthracene group instead of using a lithiated phosphine as shown in Scheme 8. This method produced a large number of products as determined by ${ }^{31} \mathrm{P}$ NMR spectroscopy and was abandoned.

Scheme 8. Attempted Synthesis of ((9-anthracenyl)- $\left.\mathrm{CH}_{2}\right) \mathbf{P h}_{2} \mathbf{P}$ (10) by Method 3

Method 4 was a modification of a literature procedure to produce tripodal $\mathrm{CH}_{3} \mathrm{CC}\left(\mathrm{CH}_{2} \mathrm{PPh}_{2}\right)_{3}{ }^{33}$ (Scheme 9). The product solution contained several products. The solid product contained mainly the sodiated oxide as determined by mass spectrometry.

Scheme 9. Attempted Synthesis of ((9-anthracenyl)- $\left.\mathrm{CH}_{2}\right) \mathbf{P h}_{2} \mathbf{P}$ (10) by Method 4

### 2.4 Conclusion

Three previously unreported phosphinimines, ((9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6), and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8), were synthesized from the respective phosphines and are moisture sensitive. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) reacts with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ to produce [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$ (3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$(4), respectively. $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$(4) are stable to moisture and oxygen both as solids and in solution. The crystal structures of both are reported and they are isostructural. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) was reacted with sodium benzoate to produce [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right][$benzoate] (5). [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right][$benzoate $]$(5) was not stable and reacted further to form anthraquinone crystals and a variety of products containing phosphorous. (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{6})$ and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ were reacted with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$ to produce [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7) and $\left[(\right.$ p-COOMe $\left.) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(9), respectively. [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$ (7) and $\left[(p-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(9) were not stable in solution. The instability of [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7) reduces the usefulness of (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ as an extractant and eliminates the use of the napthyl group as a reporter moiety. In addition to the instability of $\left[(\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(9), (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ also hydrolyzes quickly in air, eliminating it as a useful extractant. Attempted synthesis of ((9-anthracenyl)- $\left.\mathrm{CH}_{2}\right) \mathrm{Ph}_{2} \mathrm{P}(\mathbf{1 0})$ by four different methods did not produce ((9anthracenyl) $\left.-\mathrm{CH}_{2}\right) \mathrm{Ph}_{2} \mathrm{P}(\mathbf{1 0})$. While the synthesis of ((9-anthracenyl) $\left.-\mathrm{CH}_{2}\right) \mathrm{Ph}_{2} \mathrm{P}(\mathbf{1 0})$ is
probably not impossible, it is not straight forward by common methods to produce derivatized phosphines.

## CHAPTER 3: RADIOCHEMISTRY

### 3.1 Introduction

Phosphinimines hydrolyze to form the phosphiniminium cation, $\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$, which can form an ion pair with an anion to stabilize the charge (Scheme 1). $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]^{23}$ and $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]^{22}$ are known and the crystal structures have been reported. Preliminary studies on the selectivity of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ for $\mathrm{TcO}_{4}{ }^{-}$ through the formation of $\left[\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$have been reported. ${ }^{24}$ This study suggested that the selectivity of the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) for $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions was excellent and further investigations were warranted. In studies performed here, the selectivity of phosphiniminium cations of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1), (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6), and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ for $\mathrm{TcO}_{4}{ }^{-}$was challenged with a variety of anions including $\mathrm{Cl}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{I}^{-}$, acetate, and benzoate. In addition to selectivity studies, studies were undertaken to investigate the optimal conditions for the formation of the $\left[\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}^{-}\right]$ion pair including solvent and solid phase extraction studies, column capacity through concentration and volume changes, and competition with macroscopic quantities of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$.

### 3.2 Experimental

General Considerations. Caution! ${ }^{99}$ Tc emits a $0.292 \mathrm{MeV} \beta^{-}$with a half-life of $2.15 \times 10^{5}$ years, ${ }^{99 m}$ Tc emits a $140 \mathrm{keV} \gamma$-ray with a half-life of 6.0 h , and ${ }^{186}$ Re emits a $137 \mathrm{keV} \gamma$-ray and a $1.07 \mathrm{MeV} \beta^{-}$with a half-life of 90 h . Although common laboratory glassware provides adequate shielding for ${ }^{99}$ Tc , standard radiation safety procedures
must be used at all times. ${ }^{99 m}$ Tc and ${ }^{186}$ Re should be handled only in a controlled environment by qualified personnel trained in radiation safety.

Materials. ${ }^{99 \mathrm{~m}} \mathrm{Tc}$ was eluted with normal saline as sodium pertechnetate from a ${ }^{99} \mathrm{Mo} /{ }^{99 \mathrm{~m}} \mathrm{Tc}$ generator (Bristol Myers Squibb or Mallinckrodt Medical, Inc.). ${ }^{186} \mathrm{Re}$ was produced at the University of Missouri Research Reactor (MURR) from a 96.4\% enriched ${ }^{185} \mathrm{Re}$ target. ${ }^{99} \mathrm{Tc}$ was obtained from Oak Ridge National Laboratory as ammonium pertechnetate and used as a macroscopic carrier in experiments where noted. Ammonium perrhenate was purchased from Strem and used as a macroscopic carrier in experiments where noted. Dichloromethane, chloroform, hydrochloric acid, sulfuric acid, nitric acid, phosphoric acid, sodium fumerate, lactic acid, benzoic acid, acetic acid, sodium iodide, sodium chloride, sodium fumerate, and sodium hydroxide were all used as purchased. Hydriodic acid was used as purchased, in the absence of stabilizers. Silica gel was obtained from J. T. Baker, heated to $110^{\circ} \mathrm{C}$ overnight in an oven and used without further purification. Only doubly distilled water was used. Unless noted, all common laboratory chemicals were of reagent grade or better.

All samples containing both ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$were counted with a HPGe semiconductor detector with Canberra electronics and Maestro multichannel analysis software (EG\&G Ortec, Inc.). Energy calibrations were based on a ${ }^{57} \mathrm{Co},{ }^{137} \mathrm{Cs},{ }^{60} \mathrm{Co}$ mixed source. Samples containing ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$were counted on a $\mathrm{NaI}(\mathrm{Tl})$ well detector with Canberra electronics and a SCA with a Counter/Timer setup. Liquid scintillation analysis was used to verify any concentrations for ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$. Liquid scintillation counting (LSC) was performed on a Tracor Analytic Delta 300 Liquid Scintillation System. Thin layer chromatography (TLC) to verify ${ }^{99} \mathrm{Tc}$ was present as ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$was performed on a

BioScan System 200 Imaging Scanner. Paper TLC (purchased from Whatman, 1 Chr chromatography paper) was performed for each sample in saline and in diethyl ether. $\mathrm{TcO}_{2}$ is a colloid and stays at the origin $\left(\mathrm{R}_{\mathrm{f}}=0\right)$ regardless of solvent. $\mathrm{TcO}_{4}{ }^{-}$moves with the solvent front in saline $\left(R_{f}=1\right)$ and remains at the origin in ether $\left(R_{f}=0\right)$.

General Solvent Extraction Competition Procedure. The aqueous phase consisted of the desired anion $(0.15 \mathrm{M})$ containing approximately $1 \mu \mathrm{Ci}$ of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$and $5 \mu \mathrm{Ci}$ of ${ }^{186} \mathrm{ReO}_{4}^{-}$. The organic phase consisted of $5 \mathrm{mg} / \mathrm{mL}$ of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$. The organic phase $(5 \mathrm{~mL})$ and the aqueous phase $(1 \mathrm{~mL})$ were mixed by vortexing in a test tube for 2 minutes and then separated by centrifugation for 10 minutes. Aliquots (75-220 $\mu \mathrm{L})$ of each phase were taken and counted. The solution acidity ( $1 \mathrm{mM}, 0.1 \mathrm{M}, 0.15 \mathrm{M}$, $0.2 \mathrm{M}, 0.5 \mathrm{M}, 1 \mathrm{M}, 2 \mathrm{M})$, phosphinimine concentration $(0.34 \mathrm{mg} / \mathrm{mL}, 1 \mathrm{mg} / \mathrm{mL}, 3$ $\mathrm{mg} / \mathrm{mL}, 4 \mathrm{mg} / \mathrm{mL}, 5 \mathrm{mg} / \mathrm{mL}, 10 \mathrm{mg} / \mathrm{mL}$ ), vortex time ( $30 \mathrm{~s}, 1 \mathrm{~min}, 2 \mathrm{~min}$ ), centrifugation time ( $5 \mathrm{~min}, 10 \mathrm{~min}$ ), and aqueous/organic phase volumes ( $100 \mu \mathrm{~L} / 5 \mathrm{~mL}, 500 \mu \mathrm{~L} / 5$ $\mathrm{mL}, 1 \mathrm{~mL} / 5 \mathrm{~mL}, 2.5 \mathrm{~mL} / 5 \mathrm{~mL}, 5 \mathrm{~mL} / 5 \mathrm{~mL}$ ) were all optimized (data contained in Appendix 2). Solutions where prepared fresh daily. All data points were performed in triplicate.

General Solid Phase Extraction Competition Procedure. Silica was pre-dried overnight at $110{ }^{\circ} \mathrm{C}$ in an oven. Phosphinimine $\left(\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})\right.$, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6), or (p-COOMe) $\left.\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8)\right)(0.5 \mathrm{~g})$ was then sorbed onto 5 g of dried silica gel from a chloroform or dichloromethane slurry. This was allowed to slowly dry over 3 or more days in a desiccator (to prevent hydrolysis). Columns were prepared from plastic disposable columns (Fisher) containing small plastic frits, which were each filled with 0.5
g of the coated silica. One mL of the aqueous phase of the desired anion and containing approximately $1 \mu \mathrm{Ci}^{99 \mathrm{~m}} \mathrm{TcO}_{4}^{-}$and $3 \mu \mathrm{Ci}^{186} \mathrm{ReO}_{4}^{-}$was added to the top of the dry column. This was allowed to elute through the column and the effluent was collected until no more aqueous phase eluted. This was then washed with four 1 mL aliquots of the desired aqueous phase without radioactivity, with each fraction collected separately. All 5 column fractions and the column were then counted. The first fraction did not contain a full 1 mL as much of this went to wetting the column. All data points were performed in triplicate.

General Solid Extraction 1:1 Competition Procedure. The general solid phase extraction competition procedure was followed using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) with the addition of $1 \mathrm{mM}{ }^{99} \mathrm{TcO}_{4}{ }^{-}$or $10 \mathrm{mM} \mathrm{ReO}_{4}{ }^{-}$carrier added to the first mL of aqueous phase containing the desired anion with approximately $1 \mu \mathrm{Ci}$ of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$and $3 \mu \mathrm{Ci}$ of ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$. The permetallate ( ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$or ${ }^{185 / 187} \mathrm{ReO}_{4}{ }^{-}$) was added as the ammonium salt. The concentration of $\mathrm{NH}_{4} \mathrm{TcO}_{4}$ was verified by liquid scintillation analysis. The ionic strength was kept constant by varying the concentration of NaCl . When no other anions were present, 0.15 M NaCl was used. Sodium acetate or sodium iodide, 10 mM , was then added to 0.14 M NaCl to make up the aqueous phase. All experiments were performed in triplicate.

General Concentration Column Capacity Procedure. The general solid phase extraction competition procedure using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ was followed with ${ }^{99} \mathrm{TcO}_{4}^{-}$ carrier added to the first mL of aqueous phase containing 0.15 M NaCl with approximately $1 \mu \mathrm{Ci}$ of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$and $3 \mu \mathrm{Ci}$ of ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$. Pertechnetate was added as $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ in $0.11 \mathrm{mM}, 0.52 \mathrm{mM}, 1 \mathrm{mM}$, and 5.2 mM concentrations as noted. The
concentration was verified by liquid scintillation analysis. All experiments were performed in triplicate.

General Volume Column Capacity Procedure. Columns of phosphinimine coated silica were prepared using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) as in the general solid phase extraction competition procedure. The aqueous phase of $0.15 \mathrm{M} \mathrm{NaCl}, 1.3 \mathrm{mM}$ $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$, and approximately $1 \mu \mathrm{Ci}$ of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$was added to the top of the dry column in 1 mL aliquots. Each aliquot was allowed to elute and the eluent and column were counted. This was repeated until the eluent fraction began to show counts above background, which occurred at 6 mL total volume. Then each column was washed with 1 mL of 0.15 M NaCl .

### 3.3 Results and Discussion

The goal of this project is to use phosphinimines, $\mathrm{R}_{3} \mathrm{P}=\mathrm{N}-\mathrm{SiMe}_{3}$, as extractants to preconcentrate $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions for analysis or cleanup of environmental samples or cleanup of nuclear waste samples. The selectivity of the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) for $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$was investigated by challenge with a variety of anions in large excess, with anions that were equimolar, under different pH conditions, and under both solvent extraction and solid phase extraction conditions. The selectivity the phosphiniminium cation of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$, and (p-COOMe) $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8) for $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$ was investigated by challenge with a variety of anions in large excess. $\mathrm{HReO}_{4}$ and $\mathrm{HTcO}_{4}$ are both strong acids in aqueous solution with $\mathrm{pK}_{\mathrm{a}}<0 .{ }^{34}$ In solution both are dissociated to form $\mathrm{ReO}_{4}{ }^{-}$and $\mathrm{TcO}_{4}{ }^{-}$.

Solvent Extraction. $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) was dissolved in chloroform and contacted with an aqueous solution containing ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-},{ }^{186} \mathrm{ReO}_{4}{ }^{-}$, and 0.15 M of either $\mathrm{HCl}, \mathrm{HNO}_{3}, \mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HI}, \mathrm{NaCl}$, or $\mathrm{NaOH} . \mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$are not soluble in chloroform so that any radioactivity extracted into the organic phase is the result of ion pair formation. The results are shown in Figure 3 and Table 5. Greater than $95 \%$ of the ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and $>92 \%$ of the ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$radioactivity was extracted into the organic phase under acidic conditions in the presence of $\mathrm{Cl}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}$, and $\mathrm{HSO}_{4}{ }^{-} / \mathrm{SO}_{4}{ }^{2-}$. Under neutral conditions using NaCl , the percent of the ion pair formed was significantly lower due to partial secondary hydrolysis to the phosphine oxide (Scheme 2). Under basic conditions $(\mathrm{pH} \approx 12.5)<7 \%$ of the radioactivity was extracted for either ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}^{-}$ or ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$due to secondary hydrolysis to the phosphine oxide. Under acidic conditions
the positively charged $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$is stabilized, whereas under neutral and basic conditions the secondary hydrolysis to the phosphine oxide is promoted. $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{O}$ is not charged and cannot form the ion pair, thereby reducing the amount of anion that can be extracted.

Iodide was used as a positive control because it does compete with ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$to some extent. Injection of $\mathrm{Na}^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$intravenously results in ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$uptake in the thyroid, salivary glands, gastic mucosa, and the choroid plexus of the brain. ${ }^{35}$ These are the same organs that take up ${ }^{131} \mathrm{I}^{-} .{ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$can be used to image the thyroid for its structure ${ }^{36,37}$ and to test thyroid function. ${ }^{37,38}$ Iodide and $\mathrm{TcO}_{4}{ }^{-}$behave similarly in the body due to a similarity in size and charge. ${ }^{35,37,39}$ However, while they are taken up similarly in the body based on electrostatics, the pertechnetate is not metabolized in the same way and the thyroid does not incorporate it to produce iodine containing hormones. ${ }^{40}$ Figure 3 also shows that ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$is retained better than ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$which will be discussed later. The phosphinimine is not stable in solution and hydrolyzes to the phosphine oxide overnight in chloroform when exposed to air.

| :--- | :---: | :---: |
| 0.15 M HCl | $99.4 \pm 0.1$ | $99.30 \pm 0.06$ |
| $0.15 \mathrm{M} \mathrm{HNO}_{3}$ | $95.6 \pm 0.9$ | $92 \pm 1$ |
| $0.15 \mathrm{M} \mathrm{H}_{3} \mathrm{PO}_{4}$ | $99.1 \pm 0.5$ | $99.72 \pm 0.07$ |
| $0.15 \mathrm{M} \mathrm{H}_{2} \mathrm{SO}_{4}$ | $95.0 \pm 0.9$ | $92 \pm 2$ |
| 0.15 M HI | $75 \pm 3$ | $63 \pm 4$ |
| 0.15 M NaCl | $37 \pm 5$ | $26 \pm 4$ |
| 0.15 M NaOH | $7 \pm 3$ | $5 \pm 2$ |

Solid Phase Extraction Competition Studies. Columns were prepared from phosphinimine coated silica. An aqueous solution containing ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-},{ }^{186} \mathrm{ReO}_{4}{ }^{-}$, and 0.15 M of either $\mathrm{HCl}, \mathrm{HNO}_{3}, \mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HI}, \mathrm{NaCl}, \mathrm{NaI}, \mathrm{NaOH}$, sodium fumerate,
sodium benzoate, sodium lactate, or sodium acetate was added to the column and allowed to elute. The column was then washed with the same solution without ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$or ${ }^{186} \mathrm{ReO}_{4}^{-}$. There was no difference in results for $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ if the column was prewashed with the desired anion. A solution of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$in 0.15 M HCl was added to a column of pure silica, and no $\mathrm{TcO}_{4}{ }^{-}$adhered to the silica indicating that the phosphinimine was responsible for $\mathrm{TcO}_{4}{ }^{-}$binding. The activity extracted onto the column is present as the ion pair.

The phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) extracted $99 \%$ of the radioactivity onto the column under acidic conditions and in competition with HCl , $\mathrm{HNO}_{3}, \mathrm{H}_{3} \mathrm{PO}_{4}, \mathrm{H}_{2} \mathrm{SO}_{4}$, and NaCl . Under neutral conditions this was also seen for sodium fumerate with ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-} . \mathrm{HI}, \mathrm{NaI}$, sodium acetate, sodium lactate, and sodium benzoate competed with both ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$, and sodium fumerate competed with ${ }^{186} \mathrm{ReO}_{4}^{-}$ . This is seen in Figure 4 from the large reduction in the amount of activity bound to the column. NaOH also prevents binding of $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$due to secondary hydrolysis of the phosphinimine to the phosphine oxide. Figure 4 shows that ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$is retained better than ${ }^{186} \mathrm{ReO}_{4}^{-}$, which will be discussed later. When sorbed onto the silica, the phosphinimine is stable for weeks or longer. Coating onto the silica stabilizes the phosphinimine to some degree, as suggested from the overall improvement in extraction ability over the solvent extraction method. During solvent extraction, dissolved phosphinimine comes into contact with water, which can result in hydrolysis to the phosphiniminium cation and further hydrolysis to the phosphine oxide. During solid phase extraction, the phosphinimine is not dissolved and is not soluble in water. This
insolubility limits the exposure of the phosphinimine or phosphiniminium cation to water and further hydrolysis.

Figure 4. Solid Phase Extraction - Percentage of ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$ Remaining on Column for $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(1)$

Table 6. Solid Phase Extraction - Percentage of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$ Remaining on Column for $\mathbf{P h}_{3} \mathbf{P}=\mathrm{NSiMe}_{3}(1)$

Using the phosphiniminium cation of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) or (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$, under acidic and neutral conditions and in competition with $\mathrm{HCl}, \mathrm{HNO}_{3}, \mathrm{HI}, \mathrm{NaCl}, \mathrm{NaI}$, sodium acetate, and sodium benzoate, $>98 \%$ of the ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$ was bound to the column. Under acidic and neutral conditions and in competition with $\mathrm{HCl}, \mathrm{HNO}_{3}, \mathrm{NaCl}$, sodium acetate, and sodium benzoate $>98 \%$ of the ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$was bound to the column. HI and NaI competed somewhat with ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$, showing a small reduction in activity bound to the column as seen in Figures 5 and 6. This is in direct contrast to the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ where $\mathrm{HI}, \mathrm{NaI}$, acetate, benzoate, and lactate (Figure 4) all competed significantly, with only $10-85 \%$ of ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$
extracted, depending on the challenging anion. Figures 5 and 6 also show that ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$ is retained better than ${ }^{186} \mathrm{ReO}_{4}^{-}$, which will be discussed below.

Figure 5. Solid Phase Extraction - Percentage of ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$ Remaining on Column for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2)

Table 7. Solid Phase Extraction - Percentage of ${ }^{99 m} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$ Remaining on Column for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2)

Solid Phase Extraction 1:1 Competition Studies. Columns were prepared from phosphinimine coated silica. An aqueous solution containing ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-},{ }^{186} \mathrm{ReO}_{4}{ }^{-}$, and 1 $\mathrm{mM} \mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ or $10 \mathrm{mM} \mathrm{NH}_{4} \mathrm{ReO}_{4}$ and the competing anion was added to the column and allowed to elute. The competing anion was either none (just NaCl ), 10 mM sodium acetate, or 10 mM NaI . The column was washed with the same solution without any carrier, ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}^{-}$or ${ }^{186} \mathrm{ReO}_{4}^{-}$. In the previous studies (solvent extraction and solid phase
extraction), the tracer concentration was approximately $10^{-12} \mathrm{M}$ whereas the competing anions were all present at 0.15 M . In order to see if the competition effect was real or due to the large excess of competitor, the most effective organic competitor (acetate) and the most effective inorganic competitor (iodide) were added in equimolar concentration to either the ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$or $\mathrm{ReO}_{4}{ }^{-}$carrier. NaCl was also tested as a comparison since NaCl did not affect the $\mathrm{TcO}_{4}{ }^{-}$or $\mathrm{ReO}_{4}{ }^{-}$and was used to keep the ionic strengths constant with the acetate and iodide binding studies. As seen in Figure 8, within error, the acetate and iodide do not compete with $\mathrm{TcO}_{4}{ }^{-}$or $\mathrm{ReO}_{4}{ }^{-}$. The phosphiniminium cation is specific for $\mathrm{TcO}_{4}{ }^{-}$or $\mathrm{ReO}_{4}{ }^{-}$over acetate and iodide. The results are shown in Figure 8 and Table 10.

Figure 8. 1:1 Competition experiment using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(1)$ with $1 \mathbf{~ m M ~ N H} 4{ }^{99} \mathrm{TcO}_{4}$ or $10 \mathrm{mM} \mathrm{NH}_{4} \mathrm{ReO}_{4}$

All data points contain $1 \mathrm{mM} \mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ or $10 \mathrm{mM} \mathrm{NH}_{4} \mathrm{ReO}_{4}$. Ionic strength was kept constant in all samples at 0.16 M .

Table 10. 1:1 Competition experiment using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(1)$ with 1 mM $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ or $10 \mathrm{mM} \mathrm{NH}_{4} \mathrm{ReO}_{4}$ Percentage of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$and ${ }^{186} \mathrm{ReO}_{4}{ }^{-}$Remaining on Column

Column Capacity. The column capacity was tested under two different sets of conditions: (1) the concentration of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$was increased keeping the volume constant at 1 mL , and (2) the concentration of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$in 1 mL remained constant and successive 1 mL aliquots of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$solution were added to the column. The concentration determination showed that approximately $0.1 \mathrm{mM}^{99} \mathrm{TcO}_{4}{ }^{-}$could be added to the column before breakthrough occurred. As the concentration of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$, increased breakthrough became more severe. The volume determination showed that approximately 5 to 6 mL of $0.1 \mathrm{mM}^{99} \mathrm{TcO}_{4}{ }^{-}$could be added to the column before breakthrough occurred. Each column contained a theoretical maximum of $0.1 \mathrm{mmol}_{\mathrm{Ph}}^{3} \mathbf{P}=\mathrm{NSiMe}_{3}(\mathbf{1})(0.5 \mathrm{~g} /$ column, $10 \%$ loading phosphinimine) if the coating was complete (no coating of glassware) and no phosphinimine degraded to the phosphine oxide. In case (1), 1 mL of $0.1 \mathrm{mM} \mathrm{TcO}_{4}^{-}$ has $1 \times 10^{-4} \mathrm{mmol}$ of $\mathrm{TcO}_{4}^{-}$while 6 mL of $0.1 \mathrm{mM} \mathrm{TcO}_{4}^{-}$has $6 \times 10^{-4} \mathrm{mmol}^{-1} \mathrm{TcO}_{4}{ }^{-}$(case (2)). The phosphinimine is present in large excess in both cases. Using a larger volume of dilute ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$allowed more ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$to be taken up on the column. This would be a
situation similar to an environmental water sample where the ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$concentration is very small. A small volume of increasing concentrations of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$resulted in increasing breakthrough. This situation would be similar to a nuclear waste sample where the ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$concentration could be quite high. The breakthrough problem could then be solved by increasing the column size or the amount of phosphinimine on the column. The difference in elution profiles for dilute and concentrated samples is not unexpected. Ion-exchange resins often show similar elution profiles. The ion is in equilibrium between the mobile and stationary phases. Dilute samples have access to many exchange sites and travel slowly down the column increasing the separation capability of the column. Concentrated samples quickly fill and block exchange sites so the ions travel quickly and reduce separation. ${ }^{41}$ While the phosphinimine coated silica is not an ionexchange resin, the phosphinimine is forming ion pairs that associate and dissociate at a certain rate in a very similar process to ion-exchange. The results for the concentration determination are shown in Figure 9 and Table 11. The results for the volume determination are shown in Figures 10 and 11.

$\mathbf{T c O}_{4}{ }^{-}$vs. $\mathrm{ReO}_{4}{ }^{-}$. In each data set tested, the phosphinimine demonstrated a preference for $\mathrm{TcO}_{4}{ }^{-}$over $\mathrm{ReO}_{4}{ }^{-}$. Both anions have the same charge and almost the same size. The ionic radii are $0.37 \AA$ and $0.38 \AA$ for $\mathrm{Tc}(\mathrm{VII})$ and $\operatorname{Re}(\mathrm{VII})$, respectively. ${ }^{32}$ The $\mathrm{M}=\mathrm{O}$ distance is $1.69 \AA$ for both $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-22,23} \mathrm{ReO}_{4}{ }^{-}$is often used as a surrogate for $\mathrm{TcO}_{4}{ }^{-}$since it is not radioactive and often assumed to have the same chemistry due to the similarity in size and charge. ${ }^{42}$ If the formation of the ion pair is an electrostatic interaction and if it is the size to charge ratio that makes it specific for $\mathrm{TcO}_{4}{ }^{-}$, then it should have an equal specificity for $\mathrm{ReO}_{4}{ }^{-}$. The bowl shaped cyclotriveratrylene (CTV) molecules have also been reported to be more selective for $\mathrm{TcO}_{4}{ }^{-}$than $\mathrm{ReO}_{4}{ }^{-43,44}$ For the same size and charge, both $\mathrm{TcO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$should fit into the bowl in the same manner, but this was not found experimentally. $\mathrm{TcO}_{4}{ }^{-}$was always extracted into nitromethane inside the CTV better than $\mathrm{ReO}_{4}^{-}, 84 \%$ vs. $71 \%$, respectively. In the literature there are occasional reports where Tc and Re are not identical. ${ }^{42}$ An example of this is $\mathrm{Tc}_{2} \mathrm{O}_{7}{ }^{45}$ and $\mathrm{Re}_{2} \mathrm{O}_{7}\left(\mathrm{OH}_{2}\right)_{2}{ }^{46}$. In the crystal structure of $\mathrm{Tc}_{2} \mathrm{O}_{7}$ all the Tc atoms are tetrahedral $\mathrm{TcO}_{4}{ }^{-}$with one oxo group bridging the two Tc centers. $\mathrm{Re}_{2} \mathrm{O}_{7}\left(\mathrm{OH}_{2}\right)_{2}$ is an extended lattice of alternating $\left[\mathrm{ReO}_{4}\right]$ and octahedral $\left[\mathrm{ReO}_{6} \mathrm{H}_{2}\right]$ bound through bridging oxo groups (Scheme 10), with the coordination sphere expanded to include two water molecules. In this instance only $50 \%$ of all the Re is tetrahedral. Neither of the extraction results with the phosphinimine or CTV can be explained by $\mathrm{ReO}_{4}{ }^{-}$having a tetrahedral shape alone. Both sets of results can be explained by some fraction of the Re present having an octahedral coordination sphere. An octahedral coordination sphere would distort the size to charge ratio and result in the preference for $\mathrm{TcO}_{4}{ }^{-}$. Since not every Re would be octahedral and it is in a transient equilibrium, only a slight preference is observed for
$\mathrm{TcO}_{4}{ }^{-}$. The tetrahedral shape is shown in the crystal structures since the most stable form crystallizes. This structure is not always representative of solution behavior.

## Scheme 10. $\mathrm{Tc}_{2} \mathrm{O}_{7}$ and $\mathrm{Re}_{2} \mathrm{O}_{7}\left(\mathrm{OH}_{2}\right)_{2}$

Note: two of the oxygens around the octahedral Re are water groups.

### 3.4 Conclusions

Under solvent extraction conditions, the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ is selective for $\mathrm{TcO}_{4}{ }^{-}$over other inorganic anions that are common in the environment and over $\mathrm{ReO}_{4}{ }^{-}$. The iodide ion competes well due to its size and charge, but is not an environmentally common ion. Basic and neutral conditions promote a secondary hydrolysis so that solvent extraction experiments must be done under acidic conditions. Solvent extraction is not desirable since it must be done under acidic conditions, the phosphinimine is not stable in solution, and would generate mixed waste if ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$was used. Under solid phase extraction conditions, the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) shows an even better selectivity for $\mathrm{TcO}_{4}{ }^{-}$than under the solvent extraction conditions. The solid phase extraction experiments also show that the
pH window has been expanded to include neutral conditions. Basic conditions still promote a secondary hydrolysis reaction. The solid phase extraction experiments with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ also showed that a variety of organic anions compete well with $\mathrm{TcO}_{4}{ }^{-}$, which would be a serious drawback for many environmental samples. Phosphinimines (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) and (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) overcome this drawback and show that for $\mathrm{TcO}_{4}{ }^{-}$, none of the anions tested were able to compete and the phosphiniminium cations are selective for $\mathrm{TcO}_{4}^{-}$. The phosphiniminium cation of (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ has selectivity problems similar or more severe than $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$, and would not make a suitable extractant in its present form. The 1:1 competition experiments with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) showed that for organic and inorganic anions that do compete with $\mathrm{TcO}_{4}^{-}$when in large excess, they do not compete with $\mathrm{TcO}_{4}{ }^{-}$ when in equal concentrations. The column capacity studies show that the phosphinimine columns are able to hold significantly larger amounts of $\mathrm{TcO}_{4}{ }^{-}$when it is added in a dilute solution versus a concentrated solution. Based on high selectivities of the phosphiniminium cations of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1), (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), and (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ for $\mathrm{TcO}_{4}{ }^{-}$even in the presence of many other anions, phosphinimines may be useful for the removal of $\mathrm{TcO}_{4}{ }^{-}$from both environmental samples and nuclear waste samples.

## CHAPTER 4: FLUORESCENCE / SCINTILLATION SENSOR DESIGN

### 4.1 Introduction

Sensors produce a qualitative or quantitative signal that can be measured in recognition of or binding by a specific analyte. ${ }^{6,7}$ Different types of sensors can be distinguished by the type of analyte detected (i.e., cation, anion) and the type of signal generated (i.e., fluorescence, luminescence). ${ }^{8}$ In Chapter 3: Radiochemistry, the ability of several phosphinimines to extract $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions was demonstrated. Phosphinimines are capable of forming anion sensors based on this selectivity. However, a functioning sensor requires a signal to be generated in the presence of the correct anion.

Fluorescence and scintillation sensing involve the emission of light by a fluor. In fluorescence, once the anion of choice is bound to the phosphinimine the fluorescent signal would be generated, quenched, or shifted in wavelength. The result would be a difference between the original fluorescent signal without the anion and the signal with the anion bound.

Scintillation is fluorescent emission by a fluor that has been excited by an energy transfer from a radionuclide. All the energy from each nuclear emission, in this case $\beta^{-}$ emission, is transferred to the fluor, which then emits light, or scintillates. Technetium99 is a $\beta^{-}$emitting radionuclide and scintillation can be a method of signal generation when ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$is in the presence of a fluor. Since $\mathrm{TcO}_{4}{ }^{-}$should be the only $\beta^{-}$emitting anion present, the influence of other anions on the fluor itself is unimportant as long as the sensor is selective for $\mathrm{TcO}_{4}{ }^{-}$.

Phosphinimines, $\mathrm{R}_{3} \mathrm{P}=\mathrm{N}-\mathrm{SiMe}_{3}$, hydrolyze in the presence of water to the phosphiniminium cation, $\mathrm{R}_{3} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$, that can be used as extractants for the separation and preconcentration of $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions. The fluorescence and scintillation properties of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) were investigated as a possible method of signal generation in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$. In addition to a reporter group attached to the phosphinimine, $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) were each investigated in the presence of an external scintillator.

### 4.2 Experimental

General Considerations. Caution! ${ }^{99}$ Tc emits a $0.292 \mathrm{MeV} \beta^{-}$with a half-life of $2.15 \times 10^{5}$ years and ${ }^{99 m}$ Tc emits a $140 \mathrm{keV} \gamma$-ray with a half-life of 6.0 h . Although common laboratory glassware provides adequate shielding for ${ }^{99}$ Tc , standard radiation safety procedures must be used at all times. ${ }^{99 m}$ Tc should be handled only in a controlled environment by qualified personnel trained in radiation safety.

Materials. Technetium-99m was eluted with normal saline as sodium pertechnetate from a $\left.{ }^{99} \mathrm{Mo}\right)^{99 \mathrm{~m}} \mathrm{Tc}$ generator (Bristol Myers Squibb or Mallinckrodt Medical, Inc.). Technetium-99 was obtained from Oak Ridge National Laboratory as ammonium pertechnetate and used as a macroscopic carrier in experiments where noted. HPLC grade dichloromethane and toluene, and sodium chloride were purchased from Fisher Scientific. Scintillation grade anthracene was purchased from Fluka. Scintillation grade 2,5-diphenyloxazole (PPO), bis-MSB, and 1,4-bis(5-phenyloxazol-2-yl)benzene (POPOP) were purchased from Acros. Silica gel was obtained from J. T. Baker, heated to $110^{\circ} \mathrm{C}$ overnight in an oven and used without further purification. Only doubly
distilled water was used. Unless noted, all common laboratory chemicals were of reagent grade or better.

Absorbance and fluorescence emission measurements were recorded on an HP 8453 Diode-Array UV/VIS spectrometer (Santa Clara, CA) and Varian Cary Eclipse Fluorometer (Palo Alto, CA), respectively. All spectra were collected in $1 \mathrm{~cm}^{2}$ Suprasil quartz cuvettes at room temperature. Liquid scintillation counting (LSC) was performed on a PerkinElmer Tri-Carb 2900 TR Liquid Scintillation Analyzer. Samples containing ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$were counted in a $\mathrm{NaI}(\mathrm{Tl})$ well detector with Canberra electronics and a SCA with a Counter/Timer setup.

UV/Vis Absorbance and Fluorescence Measurements. A 15 W Xenon arc lamp excitation source (pulsed at 80 Hz ) was used for the fluorescence measurements. Samples were excited at 341 nm , and the emission was collected from 355-700 nm in 2 nm increments, using excitation and emission slit widths of 5 nm , a scan rate of 120 $\mathrm{nm} / \mathrm{min}$, and an averaging time of 0.5 seconds. All emission spectra were blank and absorbance corrected.

Sample preparation. Stock solutions $\left(\sim 10^{-3} \mathrm{M}\right)$ of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3), $\left[\left(9\right.\right.$-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4), anthracene, anthracene $+\mathrm{NH}_{4} \mathrm{ReO}_{4}$, anthracene $+\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$, and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ were prepared in acetonitrile $(\mathrm{ACN})$, while $\mathrm{PPh}_{2}($ anthr $)$ was prepared in dichloromethane $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ because it is not soluble in ACN. Samples $\left(\sim 10^{-5} \mathrm{M}\right)$ were prepared by quantitatively transferring known aliquots of the stock solutions into volumetric flasks and diluting to volume with toluene or liquid scintillation (LSC) cocktail (Ecosafe cocktail). All toluene samples were analyzed by UV-Vis absorbance and fluorescence
spectroscopy and liquid scintillation counting. Ecosafe cocktail samples were anlyazed by liquid scintillation counting only. All samples were prepared the day of analysis, and for liquid scintillation counting purposes, samples were allowed to sit in the dark for 30 minutes prior to analysis.

General Solid Phase Extraction Competition Procedure. Silica gel was predried overnight at $110{ }^{\circ} \mathrm{C}$ in an oven. Phosphinimine $\left(\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})\right.$ or (9anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)\right)(0.5 \mathrm{~g})$ was then sorbed onto 5 g of dried silica gel from a dichloromethane slurry. This slurry was allowed to slowly dry over 3 or more days in a desiccator (to minimize absorption of water). Columns were prepared from plastic disposable columns (Fisher) containing small plastic frits and were each filled with 0.5 g of the coated silica. One mL of 0.15 M NaCl containing approximately $0.1 \mathrm{mM}^{99} \mathrm{TcO}_{4}{ }^{-}$ and $1 \mu \mathrm{Ci}^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$was then added to the top of the dry column, and allowed to elute through the column. The effluent was collected until no more aqueous phase eluted. Then 1 mL of the particular aqueous phase containing the competitor anion but without radioactivity was added to the top of the column, and this was collected until no more aqueous phase eluted. This was repeated 3 additional times. All 5 column fractions and the column were then counted. The first fraction did not contain a full 1 mL , as most of this went to wetting the column. All data points were performed in triplicate.

General Solid Phase Extraction Scintillation Procedure. The general solid phase extraction procedure was followed. When coating the phosphinimine onto silica gel from a dichloromethane slurry, the primary scintillator (PPO) and the secondary scintillator (bis-MSB or POPOP) were added to the slurry in addition to the phosphinimine. The following weight percents compared to the silica were followed:
$10 \%$ phosphinimine, $10 \%$ primiary scintillator, $3 \%$ secondary scintillator. The weight percents were optimized and this data is presented in Appendix 3. Columns were prepared and run according to the same method as the general solid phase extraction procedure.

### 4.3 Results and Discussion

No group in the molecule $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{N}-\mathrm{SiMe}_{3}(\mathbf{1})$ is capable of generating or altering a signal in the presence of $\mathrm{TcO}_{4}^{-}$, thus requiring external groups such as PPO or anthracene to produce a scintillation signal. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) incorporates the anthracene molecule, which is a known scintillator, ${ }^{25}$ directly into the phosphinimine moiety. The fluorescence and scintillation properties of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) are reported. While (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) incorporates the alpha scintillating napthyl moiety, ${ }^{25}$ the fluorescence and scintillation properties of (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ are not reported due to the instability of [(1-napthyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(7), which degrades in solution on the order of minutes to hours.

For the fluorescence and scintillation studies of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) and its derivatives, samples $\left(10^{-5} \mathrm{M}\right)$ were prepared by diluting stock solutions $\left(10^{-3} \mathrm{M}\right)$ in toluene. These samples where analyzed by UV-Vis absorption and fluorescence spectroscopy and liquid scintillation counting (LSC). By LSC, samples $\left(10^{-5} \mathrm{M}\right)$ were counted in toluene alone and also in LSC cocktail, with a total sample volume of 10 mL . Toluene was selected since less polar solvents do not disrupt charge transfer in samples. ${ }^{47}$

Anthracene and $\mathrm{PPh}_{2}(9$ anthracenyl) both show three distinct peaks in their spectra. The spectra of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3), and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4) do not show these structural features. Rather, the features include a small peak representing the anthracene moiety and an intense broad band typically seen in charge transfer situations, see Figure 12. The phosphinimine functional group may donate electrons into the anthracene system through a conjugated network, resulting in a broad and often structureless spectrum when compared to the original fluorophore. ${ }^{10}$

If the band is indeed due to charge transfer, two mechanisms are possible. First, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) is fully conjugated, and charge transfer may occur through the bonds present in the phosphinimine. Second, as seen in other systems, photoexcited anthracene may form intramolecular excited complexes, exciplexes, with tertiary amines..$^{47,48}$ This exciplex would be the result of direct interaction of the anthracene moiety with the imine nitrogen through space. ${ }^{48}$

The intensity of this broad band is attenuated for $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4) compared to $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3), and both show a significant intensity reduction compared to (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2). Due to the lanthanide contraction, Re and Tc have almost identical sizes and thus $\mathrm{ReO}_{4}{ }^{-}$and $\mathrm{TcO}_{4}{ }^{-}$also have identical sizes. The ionic radii are $0.37 \AA$ and $0.38 \AA$ for $\mathrm{Tc}(\mathrm{VII})$ and $\operatorname{Re}(\mathrm{VII})$, respectively. ${ }^{32}$ The voltequivalents for $\mathrm{ReO}_{4}^{-}(2.588)^{34}$ and $\mathrm{TcO}_{4}^{-}(3.300)^{34}$ show that they are very similar in their oxidation-reduction potential and in their electron-withdrawing character. This similarity is seen in the small difference between the fluorescence intensity of
$\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) when compared to the significant quenching that $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4) show over (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2).

The fluorescence peak shift does not change for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3), or [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}^{-}\right]$(4). The only noticeable difference in the spectra is the reduction in the fluorescent signal with the electron-withdrawing substituents. Using this intensity attenuation or quenching of fluorescence as a sensing process can be done but is difficult. The number of attenuated fluors in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$will be small compared to the number of unattenuated fluors since the concentration of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$will be low in environmental samples. Quenching can also be caused by other factors in addition to the presence of the target analyte, ${ }^{11}$ such as chemical degredation. The attenuation or quenching of the fluorescent intensity makes (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)$ a poor candidate for a ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$sensor. The fluorescence data is shown in Figures 12 and 13.

Figure 12: Fluorescence Spectra for Anthracene, $\mathbf{P P h}_{2}$ (anthracenyl), (9anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), $\left[\left(9\right.\right.$-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3), and [(9anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4)

Figure 13. Anthracene, anthracene with $\mathrm{NH}_{4} \mathrm{TcO}_{4}$, and anthracene with $\mathrm{NH}_{4} \mathrm{ReO}_{4}$

The samples measured for fluorescence were also measured for activity by LSC in both toluene and LSC cocktail. The counting data is shown in Table 12. As expected, the samples that contain no ${ }^{99} \mathrm{Tc}$ (radioactivity) do not generate any counts above background. These samples (A-G) include a blank containing no solute (A), only anthracene (B), $\mathrm{PPh}_{2}(9$ anthracenyl $)(\mathrm{C})$, (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) (D), (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with HCl to ensure hydrolysis to (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}$(E), [(9-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) (F), and anthracene $+\mathrm{NH}_{4} \mathrm{ReO}_{4}(\mathrm{G})$. Sample (H) contains $10^{-5} \mathrm{M}$ anthracene and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$, and sample (J) contains $10^{-5} \mathrm{M}\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4). Although the total anthracene and ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$concentrations are equal in both $(\mathrm{H})$ and $(\mathrm{J}), 10^{-5} \mathrm{M}$ anthracene and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}(\mathrm{H})$ and $10^{-5} \mathrm{M}\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) (J), the count rate increased in sample (J) where the ion pair was present. This is due to the proximity of the anthracene to ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$in sample (J), whereas in sample (H) both anthracene and ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$would be distributed evenly in solution. Sample (I) contains $10^{-3} \mathrm{M}$ anthracene and $10^{-5} \mathrm{M} \mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$. The count rate increased in sample (I) compared to both samples (H) and (J) due to an increase in fluor concentration, which increases the likelihood of a beta particle interaction with the fluor. Sample (K) contains [9anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) plus $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$. The count rate is lower in [9anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) plus $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}(\mathrm{~K})$ than in $10^{-5} \mathrm{M}$ anthracene and $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}(\mathrm{H})$ and $10^{-5} \mathrm{M}\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) (J) since the anthracene is in close proximity to the nonradioactive $\mathrm{NH}_{4} \mathrm{ReO}_{4}$. Counts are still seen since $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ is present in solution with the anthracene moiety. Sample (L) contains $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ alone. The count rate for this sample (in LSC cocktail only) is significantly
higher than in sample (J) (in toluene), which contains $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right](4), 116300 \pm 117$ versus $7900 \pm 126$. The same amount of $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ is present in both samples but the count rate where anthracene is the only scintillator is significantly lower. In addition, the count rate for $10^{-5} \mathrm{M}$ $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ (in LSC cocktail only) is higher than for $10^{-5} \mathrm{M}$ $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) (in LSC cocktail). Both samples contain the same amount of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$and their count rates should be comparable or possibly higher in sample (J) (in LSC cocktail) with the additional anthracene fluor. As seen in the solid scintillation studies below, $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) may cause quenching, which would prevent light emission and lower the count rate. The trends observed with the toluene samples are also seen with the LSC cocktail samples, only with higher count rate observed as a result of the large amount of fluor present in LSC cocktail.

Table 12. Fluorescence samples prepared in toluene and LSC cocktail measured for activity

|  | Sample | cpm in Toluene | cpm in LSC cocktail |
| :---: | :---: | :---: | :---: |
| A | Blank | $41 \pm 5$ | $130 \pm 12$ |
| B | Anthracene | $47 \pm 4$ | $140 \pm 10$ |
| C | $\mathrm{Ph}_{2}(9$ anthracenyl)P | $35 \pm 5$ | $100 \pm 10$ |
| D | $\mathrm{Ph}_{2}\left(9\right.$ anthracenyl) $\mathrm{P}=\mathrm{NSiMe}_{3}$ (2) | $47 \pm 6$ | $110 \pm 9$ |
| E | [ $\mathrm{Ph}_{2}$ (9anthracenyl) $\left.\mathrm{P}=\mathrm{NH}_{2}^{+}\right]\left[\mathrm{Cl}^{-}\right]$control | $49 \pm 3$ | $240 \pm 20$ |
| F | $\left[\mathrm{Ph}_{2}\left(9\right.\right.$ anthracenyl) $\left.\mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) | $47 \pm 4$ | $120 \pm 9$ |
| G | Anthracene $+\mathrm{NH}_{4} \mathrm{ReO}_{4}$ | $50 \pm 3$ | $96 \pm 8$ |
| H | Anthracene ( $10^{-5} \mathrm{M}$ ) $+\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}\left(10^{-5} \mathrm{M}\right)$ | $2450 \pm 29$ | $28000 \pm 125$ |
| I | Anthracene $\left(10^{-3} \mathrm{M}\right)+\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}\left(10^{-5} \mathrm{M}\right)$ | $14200 \pm 619$ | N/A |
| J | $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right](4)$ | $7900 \pm 126$ | $85000 \pm 297$ |
| K | $\begin{aligned} & {\left[\mathrm{Ph}_{2}(9 \text { anthracenyl }) \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right](3)+} \\ & \mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4} \end{aligned}$ | $1900 \pm 49$ | N/A |
| L | $\mathrm{NH}_{4}{ }^{99} \mathrm{TcO}_{4}$ | N/A | $116300 \pm 117$ |

*Note: All sample contain $10^{-5} \mathrm{M}$ unless otherwise noted. N/A = Not Applicable

In addition to using a reporter unit attached to the phosphinimines (as with (9anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2)), external reporters can also be used. The method reported here is similar to that of Egorov et. al at Pacific Northwest National Laboratory. ${ }^{14}$ Columns were prepared with either $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$
(2) alone and with either $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) in the presence of external scintillators (PPO and bis-MSB). It is necessary to use bis-MSB or POPOP as wavelength shifters for PPO since PPO does not emit light in the most sensitive wavelength region (i.e., 363 nm vs. $\sim 450 \mathrm{~nm})^{25}$ for the photomultiplier tubes. The secondary fluors bis-MSB and POPOP absorb light emitted by PPO in the presence of radioactivity and reemit it in the sensitive wavelength region. Solubility problems were encountered with POPOP (crystallized out of solution without coating the silica) and so it was not used in the preparation of the columns. Anthracene emits light in the sensitive wavelength region and does not require a secondary fluor. It could potentially be used to replace both PPO and bis-MSB.

Solutions containing ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$in 0.15 M NaCl were run through the columns to generate the phosphiniminium permetallate. The presence of ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$allowed detection using a $\mathrm{NaI}(\mathrm{Tl})$ detector to ensure the column was run properly and the data matched the extraction behavior observed in Chapter 3: Radiochemistry. The data for ${ }^{99 \mathrm{~m}} \mathrm{TcO}_{4}{ }^{-}$tracer is present in Appendix 3. The columns were placed in 20 mL LSC vials and then placed in the LSC instrument, where the scintillation properties of each column were measured over time. The scintillation data is shown in Figures 14 and 15. Silica coated with only $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ showed a count rate of $900 \pm 10 \mathrm{cpm}$ while silica coated with (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) showed a count rate of $200 \pm 31 \mathrm{cpm}$. The samples using (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), however, showed an increase in scintillation over time to approximately the same count rate as samples using $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1). This suggests that (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) is quenching the count rate and this quenching goes away over the course of approximately 1 month. Samples using
$\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) with $\mathrm{PPO} /$ bis-MSB showed a large count rate of $150,000 \pm 1319 \mathrm{cpm}$, which then decreased over the course of 1 month. If the initial large count rate was not the result of scintillation caused by ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$it could have been the result of chemoluminescence resulting in scintillation that was not the result of $\beta^{-}$particle emission. ${ }^{25}$ The decrease of the signal over time could be the result of reduction of the chemoluminescence or photobleaching of the fluor. Samples containing (9anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with $\mathrm{PPO} /$ bis-MSB showed a count rate of $3000 \pm 409$ cpm, which increased over the course of 1 month. This was still significantly lower than the samples containing $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ with $\mathrm{PPO} /$ bis-MSB, and could be due to (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) quenching the scintillation. This result is similar to the increase in the count rate with (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) alone. These results were not anticipated. Since (2) contains a known scintillator (anthracene) and was already observed to scintillate in toluene in the presence of ${ }^{99} \mathrm{TcO}_{4}^{-}$, it was expected that samples containing (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) would result in increased scintillation compared to $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) and that samples containing (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with $\mathrm{PPO} /$ bis-MSB would show increased scintillation compared to samples containing $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ and $\mathrm{PPO} /$ bis-MSB.

### 4.4 Conclusion

The fluorescence properties of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) show an intense broad band typically seen in charge transfer that is not present in anthracene or the corresponding phosphine. The intensity of this broad band is attenuated for
$\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}^{-}\right]$(3) and $\left[\left(9\right.\right.$-anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4) because of the electron-withdrawing nature of $\mathrm{MO}_{4}^{-}$. The phosphiniminium cation of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) scintillates in the presence of the beta emitting ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$ to produce a signal as demonstrated by the $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}^{2}=\mathrm{NH}_{2}{ }^{+}\right]\left[{ }^{99} \mathrm{TcO}_{4}{ }^{-}\right]$(4). Based on this result, silica was coated with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) alone or in the presence of $\mathrm{PPO} /$ bis-MSB. The results showed that (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) alone or with $\mathrm{PPO} /$ bis-MSB had a very low scintillation count rate that increased over the course of one month. $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) alone produced a very low scintillation count rate, which remained constant over time since no scintillator was present. $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) with $\mathrm{PPO} /$ bis-MSB produced a large count rate initially that decreased over the course of one month. The solid scintillator columns did not produce a steady signal over time so that (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) alone, and $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) with $\mathrm{PPO} /$ bis-MSB cannot be used to generate a scintillation sensor. This could be resolved by two different methods. First, the phosphinimine could be altered to prevent the chemoluminescence or quenching problems observed. The altered phosphinimine may also have superior selectivity for ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$. Altering the phosphinimine could include attaching different fluors in the place of anthracene or changing substituent groups so that the signal generated with external scintillators would be constant over time. Second, the external scintillator could be changed. Other scintillators, such as anthracene, are known and could be used to replace PPO or bis-MSB.

## CHAPTER 5: FUTURE GOALS

To complete the radiochemical characterization data set for $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$, several additional studies should be performed. The results for $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) show that it is stable and the phosphiniminium cation extracts $\mathrm{TcO}_{4}{ }^{-}$under acidic and neutral conditions but undergoes hydrolysis in strong base. While many environmental samples have the potential to be basic, they will not usually be strongly basic. A pH study of the stability of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) from $\mathrm{pH} 7-12$ using phosphate buffer solutions would show at what pH significant hydrolysis of the phosphinimine to the phosphine oxide begins. Expanding the pH window eliminates sample pretreatment, which would decrease waste generation and expense. After establishing the pH window for $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$, it would be valuable to investigate the pH window for (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2). Since the phosphiniminium cation of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) already shows much better selectivity for $\mathrm{TcO}_{4}{ }^{-}$over other anions, it would be useful to determine whether it is stable over a wider pH window.

Two additional anions should also be investigated with $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ and possibly with (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), bicarbonate and uranyl nitrate. $\mathrm{TcO}_{4}{ }^{-}$is known to react and form complexes with carbonates ${ }^{49,50}$ and they could interfere with $\mathrm{TcO}_{4}{ }^{-}$extraction. Due to $\mathrm{pH}, \mathrm{HCO}_{3}{ }^{-}$would be the most readily available carbonate species in the environment and the competition of this species with $\mathrm{TcO}_{4}{ }^{-}$should be investigated. Nuclear waste streams come from reprocessing of nuclear fuel and usually begin by dissolving the fuel in nitric acid. ${ }^{51}$ Depending on the specific process used, the solution undergoes a series of chemical treatments. Once uranium, in the form of uranyl nitrate, is purified, $\mathrm{TcO}_{4}{ }^{-}$is a major contaminate and handling problem. If
phosphinimines are selective for $\mathrm{TcO}_{4}{ }^{-}$over uranyl nitrate they could be used as extractants to purify nuclear waste or in reprocessing technology.

The phosphiniminium cations of phosphinimines $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) have been shown to be selective for $\mathrm{TcO}_{4}{ }^{-}$under laboratory conditions. Natural waters with a known quantity of $\mathrm{TcO}_{4}{ }^{-}$added should be tested to determine if the phosphinimines are selective under actual environmental conditions. Waters from a variety of sources around the country that are or are known to be similar to waters that are potentially contaminated should be tested.

Silica was used as a solid support in these studies due to its ready availability and low cost. Several problems exist with using silica, including instability at high and low pH , inconsistencies between manufacturers, batch numbers, and lot numbers, and severe optical quenching when using a scintillator. Other supports should be investigated that alleviate these problems. Scintillating organic fibers and beads were considered but dissolve in organic solvents, eliminating the ability to coat the phosphinimine on the surface. Porous microbeads and similar supports from companies like Eichrom may provide suitable supports for further studies.

Of the phosphinimines reported here, $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) are mildly moisture sensitive but the phosphiniminium cations form stable complexes with pertechnetate and perrhenate. (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ is mildly moisture sensitive but the phosphiniminium cation does not form a stable complex with perrhenate and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8) is extremely moisture sensitive and the phosphiniminium cation does not form stable ion pairs with perrhenate. This instabililty is shown in the degradation of the ion pair in
solution over the course of minutes to hours. Additional phosphinimine derivatives should be synthesized to test for their stability, stability of the ion pairs, and their extraction abilities. These derivatives could include additional functionalization of (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8)$ to add a polymer or reporter group, possibly increasing the stability of this phosphinimine. Derivatives could also include other types of reporter groups, multiple phosphinimine groups in a linear chain or attached to a tripodal ligand, alkyl phosphinimines to compare to the aryl phosphinimines reported here.

In addition to synthesizing other phosphinimines, a method to generate a signal is still required in order to generate a sensor. The internal anthracene reporter on (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) did not function as a suitable scintillator. Using $\mathrm{PPO} /$ bis-MSB as external reporters in the presence of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) did not generate a reliable signal. Synthesizing phosphinimines with other internal reporters such as fluorescein or utilizing other external reporters such as anthracene are possible methods to produce a reliable signal.

Once a method of producing a reliable signal is developed, a functioning sensor should be assembled or generated. It would require a sensor material that could be introduced and removed (possibly in a column format), a measurement chamber, photomultiplier tube(s), a method of processing the signal, etc. The efficiency and sensitivity would need to be measured to compare to current methods.

## CHAPTER 6: CONCLUSION

Four phosphinimines were synthesized, fully characterized, and tested radiometrically for the ability to extract $\mathrm{TcO}_{4}{ }^{-}$in the presence of a variety of other anions. Both $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) are mildly moisture sensitive but the phosphiniminium cations form stable complexes with $\mathrm{ReO}_{4}{ }^{-}$and $\mathrm{TcO}_{4}{ }^{-}$. The crystal structures of $\left[\left(9-\right.\right.$ anthracenyl) $\left.\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{ReO}_{4}{ }^{-}\right]$(3) and $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4) are reported and they are isostructural. (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{6})$ and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ are more moisture sensitive than $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), but the greatest difference is the instability of the complexes of the phosphiniminium cations with $\mathrm{ReO}_{4}{ }^{-}$. This instability makes both (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$ and (p-COOMe) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(8)$ poor choices for use in a sensor.

All four phosphinimines were tested in the presence of a variety of inorganic and organic anions. The phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ is more selective for $\mathrm{TcO}_{4}^{-}$than $\mathrm{Cl}^{-}, \mathrm{NO}_{3}^{-}, \mathrm{H}_{3} \mathrm{PO}_{4} / \mathrm{H}_{2} \mathrm{PO}_{4}^{-}, \mathrm{H}_{2} \mathrm{SO}_{4} / \mathrm{HSO}_{4}^{-}$, and fumerate. Iodide, acetate, benzoate, and lactate all compete significantly with $\mathrm{TcO}_{4}{ }^{-}$when they are in large excess. Iodide and acetate in equimolar concentration do not compete with $\mathrm{TcO}_{4}{ }^{-}$, and it is reasonable to assume that benzoate and lactate behave similarly. The phosphiniminium cations of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) and (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) showed significantly less competition of other anions with $\mathrm{TcO}_{4}{ }^{-}$than the phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1). However, they are more expensive and time consuming to produce, and the phosphiniminium perrhenate complexes with (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (6) are not stable. The phosphiniminium cation of ( $\mathrm{p}-\mathrm{COOMe}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{8})$ is
selective for $\mathrm{TcO}_{4}{ }^{-}$in the presence of some anions but the sensitivity of the phosphinimine to moisture makes it to difficult to handle.

The fluorescent and scintillation properties of (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) were investigated. The anthracene moiety does fluoresce, but the emission is significantly altered in the presence of the imine group, going from a sharp, four peak emission to a broad charge transfer band. The presence of $\mathrm{ReO}_{4}{ }^{-}$or $\mathrm{TcO}_{4}{ }^{-}$affect the emission even more significantly, reducing the intensity of emission drastically. $\left[(9-\right.$ anthracenyl $\left.) \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NH}_{2}{ }^{+}\right]\left[\mathrm{TcO}_{4}{ }^{-}\right]$(4) also scintillates in toluene in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$but shows a quenching effect of the scintillation in LSC cocktail. This quenching effect is also present in the solid phase extraction scintillation experiments. (9anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)$ alone shows less scintillation in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$ than $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ when coated onto a solid support. (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2) in the presence of $\mathrm{PPO} /$ bis-MSB shows significantly less scintillation in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$than $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}(\mathbf{1})$ in the presence of $\mathrm{PPO} /$ bis-MSB when coated onto a solid support. The most significant problem with the solid extraction scintillation experiments for either $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) or (2), either alone or in the presence of $\mathrm{PPO} /$ bis-MSB, is the lack of a reproducible signal over time. The count rate for all the samples changed over the course of a month.

The phosphiniminium cation of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1), (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (2), (1-napthyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(6)$, and ( $\mathrm{p}-\mathrm{COOMe}$ ) $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}$ (8) are selective for $\mathrm{TcO}_{4}{ }^{-}$in the presence of other anions to varying degrees. The high stability and selectivity in the presence of ${ }^{99} \mathrm{TcO}_{4}{ }^{-}$makes the phosphiniminium cations of $\mathrm{Ph}_{3} \mathrm{P}=\mathrm{NSiMe}_{3}$ (1) and (9-anthracenyl) $\mathrm{Ph}_{2} \mathrm{P}=\mathrm{NSiMe}_{3}(2)$ promising extractants for either
use in a scintillation sensor or for pertechnetate separation. This separation method is an improvement over other methods like anion-exchange chromatography in both the selectivity for $\mathrm{TcO}_{4}{ }^{-}$and in the ability to sample large volumes. Large volumes of contaminated water can be run through phosphinimine columns resulting in both preconcentration of $\mathrm{TcO}_{4}{ }^{-}$and remediation of the water. To date, preconcentration involves tedious and time consuming chemistry by a trained technician. The phosphinimines provide an easy to implement preconcentration method that could be both time and cost effective. A variety of analysis methods could then be implemented if the amount of $\mathrm{TcO}_{4}{ }^{-}$needs to be determined. Having a method that is fast and easy to implement has the benefits of reduced worker exposure to hazardous chemicals and radioactivity in addition to the reduction of chemical waste and secondary wastes like gloves, vials, etc. With further development, the column material or phosphinimine extractant could be equipped with reporter groups to determine the amount of $\mathrm{TcO}_{4}{ }^{-}$ without further analysis. If other suitable derivatives could be synthesized, a library of extractants could be formed showing which phosphinimine to use in which extraction situation or water sample.

## VITA

Leah Marie Arrigo, daughter of Glen and Ellen Russell, was born April 5, 1979 and grew up in Texas. She earned her Bachelors of Science in Chemistry from Texas A\&M University - College Station in May 2001. In August 2001, Leah began the Ph.D. program in Chemistry at the University of Missouri Columbia. She joined Dr. Paul Duval’s research group in January of 2002, working on airfree inorganic synthesis of uranyl compounds. In September 2005, Leah transferred to Dr. Silvia Jurisson's group, working on the use of phosphinimines as extractants for technetium environmental contamination. She received her Ph.D. degree in May 2007. Leah has accepted a permanent position in the Analytical Division at Savannah River National Laboratory in South Carolina.
