REGULATION AND FUNCTION OF P2Y\textsubscript{2} AND P2X\textsubscript{7} NUCLEOTIDE RECEPTORS IN THE CENTRAL NERVOUS SYSTEM

A Dissertation
Presented to
the Faculty of the Graduate School
at the University of Missouri-Columbia

In Partial Fulfillment
of the Requirements for the Degree
Doctor of Philosophy

by
QIONGMAN KONG,
Dr. Gary A. Weisman, Dissertation Supervisor

AUGUST 2007
The undersigned, appointed by the dean of the Graduate School, have examined the dissertation entitled

REGULATION AND FUNCTION OF P2Y₂ AND P2X₇ NUCLEOTIDE RECEPTORS IN THE CENTRAL NERVOUS SYSTEM

presented by Qiongman Kong,

a candidate for the degree of doctor of philosophy,

and hereby certify that, in their opinion, it is worthy of acceptance.

ACKNOWLEDGEMENTS

These projects would not have been possible without the support of many people. I would like to express my deepest gratitude to my advisor, Dr. Gary A. Weisman for his excellent guidance in both research and life, for providing me with an active laboratory atmosphere and encouraging me to work independently on the research projects with great patience, and for the great care during the long recovery term after an auto accident in 2002. I also want to thank Dr. Cheikh I. Seye, Dr. Laurie Erb, and Jean M. Camden in Weisman’s lab, and Drs. Grace Y. Sun and Agnes Simonyi in Sun’s lab for their tremendous support on my research projects.

I extend my gratitude to members of my doctoral committee: Drs. Laurie Erb, Grace Y. Sun, Mark Kirk, Dennis Lubahn and Cathy Krull, for their insightful comments and continuous guidance on my work.

I want to thank Jun Liu and Zhongji Liao, my best friends at MU, who have shared happiness with me and supported me to overcome my difficulties. I would also like to express my appreciation to many other friends at MU: Yu Ningpu, Wang Min, Qun Wang, Jennifer Lynn Hamilton, Sue Yu, Xiaolin Zhang, Brent Krugh, Olga Baker, Antje Heese, Troy Scott Peterson, Ann Schrader, Nishant Jain, Shivaji Rikka, Tixieanna Dissmore, Fernand Gendron, Sriparna Bagchi, Julie Hayes, Jessica Newton, Korey Griffin, and Richard Garrad.

Finally, I would like to thank my parents, my sister, and my boyfriend, Xin He, for their continuous love and support.

REGULATION AND FUNCTION OF P2Y\textsubscript{2} AND P2X\textsubscript{7} NUCLEOTIDE RECEPTORS IN THE CENTRAL NERVOUS SYSTEM

Qiongman Kong

Dissertation Supervisor: Dr. Gary A. Weisman

ABSTRACT

It is well known that ATP acts as a classic neurotransmitter in the central nervous system. It is stored in molar concentrations in synaptic vesicles, released upon neuronal excitation, and activates both ion channel receptors (P2X) and metabotropic receptors (P2Y) on post-synaptic cells. Activation of these nucleotide receptors then alters a variety of brain activities, such as the formation of long term memory and the perception of pain. In addition to its role as a neurotransmitter, ATP and other nucleotides are known to be released from injured or ischemic tissue and have been reported to affect inflammatory events in the brain and many other tissues, however, these inflammatory events as well as the subtype(s) of nucleotide receptor(s) influencing these events have not been well defined. This dissertation examines the expression patterns of P2X and P2Y nucleotide receptors in rat primary cortical neurons and adult rodent brain tissue. Based on these studies, particular emphasis was placed on delineating the role of the P2Y\textsubscript{2} receptor subtype in neuronal inflammation and the P2X\textsubscript{7} receptor subtype in neuronal apoptosis.

The P2Y\textsubscript{2} receptor is distinguished from other nucleotide receptor subtypes by an equal-potency for activation by ATP and UTP and its ability to be up-regulated in response to tissue injury or stress. Studies mentored by Dr. Cheikh Seye used a
collared rabbit carotid artery model to indicate for the first time a role for the P2Y$_2$R in development of intimal hyperplasia associated with atherosclerosis and restenosis (Appendix-1). In vitro studies with various cell lines (1321N1, HEK, COS7, and DITNC) in collaboration with others investigated signaling events regulated by the P2Y$_2$R, including activation of PI3K, Src, calcium mobilization, Akt, and ERK1/2 and the importance of $\alpha_v\beta_3/\beta_5$ integrin interaction with the P2Y$_2$ receptor in selective (Go but not Gq) signaling and the antagonist role of BG0136 on P2Y$_2$R activity (Appendix-2, 3).

In a gerbil transient global ischemia model, we analyzed the effect of ischemia on the in vivo expression level of P2Y$_2$R mRNA in the rodent brain by in situ hybridization and RT-PCR (Chapter 4). P2Y$_2$R mRNA was expressed at low levels in normal rodent (rat, mouse and gerbil) brain. Transient ischemia (5 min occlusion) did not affect P2Y$_2$R mRNA levels in any region of gerbil brain after various reperfusion times (4 h, 16 h and 48 h), indicating that the P2Y$_2$R was not regulated at the transcriptional level in the gerbil transient ischemia model.

The functional expression of the P2Y$_2$R was also tested in rat primary cortical neurons (rPCNs). In rPCNs after in vitro culture for 7-10 days, P2Y$_2$R mRNA and receptor activity were virtually absent in unstimulated cells, whereas overnight treatment with IL-1$\beta$ caused up-regulation of both P2Y$_2$R mRNA and receptor activity. Furthermore, activation of P2Y$_2$R in rPCNs treated with IL-1$\beta$ or transfected with P2Y$_2$R cDNA enhanced the release of sAPP$\alpha$, a secretory amyloid protein that protects neurons as an injury-induced neurotrophic factor. P2Y$_2$R-mediated sAPP$\alpha$
release from rPCNs was dependent on ADAM10/17 and PI3K activity and was partially dependent on ERK1/2 activity, but did not require activation of PKC. These results suggest that under inflammatory conditions, IL-1β evokes functional up-regulation of P2Y_2R in neurons and subsequent activation of the P2Y_2R signaling cascade results in an increase of sAPPα release through activation of the α,γ-secretase pathway (Chapter 3).

In contrast to the neuroprotective role of extracellular nucleotides just described, ATP has also been reported to cause apoptosis in a neuronal cell line by activating the P2X_7 subtype of nucleotide receptors (P2X_7R). Here, we extended the examination of P2X_7R-mediated apoptosis in rPCNs. Unlike the P2Y_2R, P2X_7R was functionally expressed in unstimulated rPCNs (indicated by RT-PCR and ATP-induced intracellular calcium mobilization). Activation of the P2X_7R via extracellular nucleotides in rPCNs caused biochemical (i.e., caspase activation) and morphological (i.e., nuclear condensation and DNA fragmentation) changes characteristic of apoptotic cell death through an intrinsic JNK1- and ERK-dependent caspase-8/9/3 activation pathway (Chapter 2).

Together, these data describe the expression patterns of P2 nucleotide receptors in rat primary cultures of cortical neurons, in adult rodent brains, in cerebral ischemia and in collared rabbit carotid arteries and demonstrate that the P2Y_2R is up-regulated in response to cytokine stimulation in rPCNs and after collar transplantation around rabbit carotid arteries. Moreover, activation of the P2Y_2R and P2X_7R in rPCNs caused α-secretase-dependent APP processing and caspase8/9/3-dependent apoptosis,
respectively, whereas \textit{in vivo} studies in the collared carotid artery model indicate that P2Y$_2$R also plays an important role in the development of intimal hyperplasia.
CHAPTER 1

INTRODUCTION

Adenosine 5’–triphosphate release

Nucleotides can be released from various sources in the nervous system include excitatory neurons, injured cells, cells undergoing mechanical or oxidative stress, aggregating platelets, degranulating macrophages, and astrocytes (Bergfeld et al., 1992; Ciccarelli et al., 1999; Ahmed et al., 2000; Ostrom et al., 2001). In addition to acting as energy sources and neurotransmitters, purines such as adenosine 5’–triphosphate (ATP) are trophic factors in both development/growth and regeneration/proliferation and neurotoxic factors in neuronal cell death of different cell types under normal physiological and developmental conditions (Burnstock and Wood, 1996; Neary et al., 1996; Vitolo et al., 1998).

P2 nucleotide receptor classification

Extracellular nucleotides bind to and activate cell surface P2 receptors. To date, these receptors have been classified into two main families: the G protein-coupled receptors (GPCRs; P2YR) and the ligand-gated ion channels (P2XR). Nine P2Y receptors have been cloned and identified as GPCRs with seven transmembrane domains coupled via G proteins (Gq/11 or Gi/o) to phospholipase C (PLC) and/or adenylate cyclase, including P2Y1, P2Y2, P2Y4, P2Y6, P2Y11, P2Y12, P2Y13, P2Y14, and P2Y15 (Sak and Webb, 2002; Inbe et al., 2004), although the P2Y15 receptor has not been conclusively established to be a P2 nucleotide receptor (Abbracchio et al.,
Seven P2X receptors have been cloned and identified as ligand-gated ion channels comprised of homo- or hetero-oligomers, including P2X₁, P2X₂, P2X₃, P2X₄, P2X₅, P2X₆, and P2X₇ (Burstock 2000). Activation of these P2 receptor subtypes in neurons and glial cells under normal and pathological conditions can mediate cell apoptosis, proliferation, migration, inflammation, ion transport, and neurotransmission (Burstock 2000; Ciccarrelli et al., 2001). Therefore, P2 receptors in the CNS might be potential targets for pharmaceutical therapies in neurological disorders. Among these P2 receptors, our research has focused on the expression and regulation of the P2Y₂R and its signaling pathways associated with α-secretase-dependent amyloid precursor protein (APP) processing, and on P2X₇R-mediated apoptosis in neurons.

Expression and regulation of P2 nucleotide receptors in the brain

In the rat brain, P2Y₁ receptor mRNA expression was detected and regulated at different embryonic and postnatal stages; P2Y₂ receptor expression was detected at P8-12 (postnatal 8-12 days; Zhu and Kimelberg, 2004) and in adult rat brain (Loesch and Glass, 2006). P2Y₄ receptor expression was detected at E14 (embryonic 14 days) and P8 (postnatal 8 days) while P2Y₆ receptor expression was detected at E14 (Webb et al., 1998; Cheung et al., 2003; Zhu and Kimelberg, 2001 and 2004; Bennett et al., 2003). P2Y₁₂ receptor expression was low on E13 and E17, but it gradually increased during development from postnatal day 0 to 6 weeks (Sasaki et al., 2003). P2X₃ receptor mRNA was detected at E11, then declined in P7 rats, and was hardly detectable in P14 animals (Kidd et al., 1998; Cheung & Burnstock, 2002). Other P2X
receptor subtypes were also detected at certain developmental stages. P2X_1R expression was detected at P7, P2X_2R expression was detected at E11 and P2X_7 receptor expression was detected at E19 (Kidd et al., 1995; Collo et al., 1997).

In primary cultures of rat cortical astrocytes obtained at different postnatal periods, P2Y_1, P2Y_2, P2Y_4 and P2X_1-P2X_4, P2X_6, and P2X_7 receptor subtypes were expressed in P1 pups (Lenz et al., 2000; Jacques-Silva et al., 2004); P2X_3, P2X_5-P2X_7 and P2Y_1, P2Y_2, P2Y_4, and P2Y_6 receptor expression was detectable in P2-P3 pups (postnatal 2-3 days; Figure 1A; Weisman et al., 2005); and all P2 receptor subtypes except P2X_6 were detected in P7 pups (Fumagalli et al., 2003). In rat primary cortical neurons obtained at E17-19 days, mRNA for P2Y_1, P2Y_4, P2Y_6, P2X_3, P2X_5, and P2X_7 receptor subtypes were present after 7-10 days in culture, whereas very low levels of P2Y_2, P2X_2 and P2X_6 receptor mRNA expression could be detected after 35 cycles of polymerase chain reaction (Figure 1B-C; Weisman et al., 2005; Kong et al., 2005). ATP and NGF have been shown to promote sustained up-regulation of various P2 nucleotide receptor subtypes including P2X_2-P2X_4 and P2Y_2 in PC12 cells under neurite regenerating (serum-containing) conditions (Rathbone et al., 1999; D’Ambrosi et al., 2001).

**P2X_7 nucleotide receptors and apoptosis**

As a mediator of cell-to-cell communication, ATP can trigger a variety of biological responses after being rapidly released in large amounts from various sources, including nerve terminals, activated glial cells, platelets, endothelial cells, antigen-stimulated T cells, and other cell types following hypoxia, stress, and tissue...
damage. (Bergfeld et al., 1992; Ciccarelli et al., 1999; Ahmed et al., 2000; Ostrom et al., 2001) For example, in human umbilical cord vein endothelial cells (HUVECs), substantial release of ATP (and UTP) is induced by shear stress (Burnstock 1999), which may lead to alterations in the balance between proliferation and apoptosis regulated by P1 adenosine and P2 (particularly P2X7) nucleotide receptors (Kaiser et al., 1997). P2X7 and P1 receptors have been previously linked to apoptosis in other cell types, including immune cells, astrocytes, and thymocytes (Zheng et al., 1991; Di Virgilio et al., 1995; Jacobson et al., 1999). The P2X7R also has been shown to mediate ATP/UTP-induced cell death in human embryonic kidney cells (Wen et al., 2003), human cervical epithelial cells (Wang et al., 2004), and primary rat cortical neurons (Chapter 2; Kong et al., 2005).

In human fibroblasts, P2X7 receptors were identified as the main nucleotide receptor involved in high glucose concentration-dependent responses modulated by ATP, including morphological changes, enhanced apoptosis, caspase-3 activation, and IL-6 release (Solini et al., 2000). In the immune system, ATP also plays important roles through nucleotide receptors in leukocyte functions. P2X7 receptor-mediated cell death has been demonstrated in various cell types, including a lymphocytic cell line, murine thymocytes, murine peritoneal macrophages, human macrophages, mesangial cells, dendritic cells, and microglial cells (Zheng et al., 1991; Zanovello et al., 1990; Lammas et al., 1997; Schulze-Lohoff et al., 1998; Coutinho-Silva et al., 1999; Ferrari et al., 1999). It also has been reported that the P2X7 receptor modulates macrophage production of TNF-α, IL-1β and NO following LPS exposure (Hu et al., 1998),
consistent with a role for the P2X\textsubscript{7} receptor in inflammation. These studies have provided compelling evidence suggesting a role for P2 receptors (especially P2X\textsubscript{7}R) in cell apoptosis in the central nervous system; however, further studies are needed to determine the precise pathways involved and to accumulate direct evidence that these pathways contribute significantly to neurodegenerative diseases and brain injury. Studies in Chapter 2 have investigated P2X\textsubscript{7} receptor-mediated apoptosis in rat primary cortical neurons and the signaling pathways involved (Kong et al., 2005).

*P2Y\textsubscript{2} nucleotide receptors in Alzheimer’s disease*

Alzheimer’s disease is an age-related neurodegenerative disorder that is characterized by progressive memory loss and deterioration of higher cognitive functions. The hallmarks of Alzheimer’s disease (AD) include extracellular plaques of aggregated β-amyloid protein (Aβ) and intracellular neurofibrillary tangles that contain hyperphosphorylated tau protein in brain neurons (Figure 2; reviewed by Drouet et al., 2000). The senile plaques contain a compact deposition of β-amyloid peptides surrounded by dystrophic neuritis, activated microglia and reactive astrocytes. The major amyloid peptides in the plaques are Aβ\textsubscript{1-42} and Aβ\textsubscript{1-40}, the 4-kDa peptides derived by proteolytic cleavage of amyloid precursor protein (APP). APP can be cleaved within the Aβ domain by the combined action of α- and γ-secretases to generate neurotrophic and neuroprotective sAPPα and a P3 fragment (Li et al., 1997; Luo et al., 2001), or undergo cleavage by β- and γ-secretases to form neurodegenerative β-amyloid peptides (Aβ\textsubscript{1-42} and Aβ\textsubscript{1-40}) (Younkin, 1998). Under normal conditions, about 90% of secreted Aβ peptides are Aβ\textsubscript{1-40}, a more soluble form
than Aβ1-42 that can be eliminated from brain and can only slowly be converted to the plaque-forming β-sheet configuration. In the AD brain, Aβ1-42 is first deposited in plaques, whereas Aβ1-40 is deposited later as the disease progresses (Iwatsubo et al., 1994). A major goal to date in the development of treatments for AD include approaches that decrease Aβ production by blocking γ-secretase activity. However, this may result in defective haematopoiesis or other side effects (e.g., inhibition of the notch signaling pathway) due to loss of γ-secretase function (Rochette and Murphy, 2002). Clearly, further studies are needed to better understand the regulation of the different APP processing enzymes (i.e., α-, β- and γ-secretases) to design effective treatments for AD.

To date, the research on the functional involvement of P2 nucleotide receptors in AD is very limited. P2X7 receptors mediate superoxide production in primary microglia and are up-regulated in a transgenic mouse model of Alzheimer's disease (Parvathenani et al., 2003). Chronic neuroinflammation is a contributor to the pathophysiology of Alzheimer's disease (AD; Eikelenboom et al., 2000; Hauss-Wegrzyniak et al., 1998). Oxidative stress and oligomeric β-amyloid (Aβ) peptide production in AD brain can increase extracellular levels of cytokines and nucleotides that activate receptors in glial cells (i.e., astrocytes and microglia) to stimulate intracellular signaling pathways and promote reactive gliosis, a universal response of the brain to injury (Mehlhorn et al., 2000). In the CNS, we reported that P2Y2 receptors mediate astrocyte migration through interactions with αV integrins in rat primary cortical astrocytes, which suggests a role for P2Y2R-mediated signaling in
regulating astrogliosis in brain disorders (Wang et al., 2005). Moreover, previous studies by our group showed that UTP enhances α- and γ-secretase-mediated APP processing in P2Y2R-transfected 1321N1 astrocytoma cells (Camden et al., 2005). However, relatively little is known about the contribution of P2Y2Rs to neuronal functions or their co-regulation with cytokine receptors of activities related to AD. Therefore, we have investigated the effect of cytokines on functional P2Y2R expression in primary cortical neurons from E18 rat embryos, as described in Chapter 3. The role of P2Y2 receptors in APP processing and the signaling molecules involved was also investigated in rat primary cortical neurons (see Chapter 3).

P2 nucleotide receptors in brain ischemia

Acute ischemic stroke is the leading cause of adult disability and also the most frequent pathogenic mechanism of brain lesion in infancy (Guzzetta et al., 2000). Interestingly, basic and clinical evidence shows that impaired cerebral perfusion originating in the microvasculature triggered most of the key pathologic events associated with Alzheimer’s disease (AD); thus the presence of a condition that lowers cerebral perfusion together with advanced aging are proposed as two factors necessary to induce a neurodegenerative process in the AD brain (de la Torre, 2000). The cerebral circulation becomes inadequate under the following conditions that often lead to global ischemia, rather than focal ischemia: 1) the perfusion pressure is reduced; 2) the vascular resistance becomes too high; or 3) the oxygen or glucose supply is reduced (Garcia, 1975). Transient global ischemia caused by a 5-minute occlusion of gerbil bilateral carotid arteries (BCAOs) leads to selective and delayed
neuronal death (DND) of CA1 pyramidal neurons (Figure 3; Kirino, 1982), associated with activation of surrounding astrocytes in the hippocampus (DeLeo et al., 1987). Transient focal ischemia for 60 min consistently resulted in a large infarct confined to the right MCA cortex in rats (Figure 3C). However, ischemic stroke cannot be mimicked satisfactorily in vitro due to its complex pathophysiology involving the interplay of many different cells and tissues including neurons, glia, endothelium, and the immune system. Thus, several animal models of global and focal brain ischemia have been developed for stroke research including the gerbil/mouse model of transient global ischemia by occlusion of both common carotid arteries (CCAs) and the rat/mouse model of focal ischemia model by middle cerebral artery occlusion (MCAO) (Traystman, 2003).

After transient global ischemia, up-regulation of P2X$_2$ and P2X$_4$ receptors was observed in neurons and microglia of gerbil hippocampus, respectively (Table 1; Cavaliere et al., 2003). P2X$_7$ mRNA was also up-regulated in cultured cerebellar granule neurons of organotypic hippocampal cultures in vitro (Cavaliere et al., 2002, 2004) and in activated microglia surrounding necrotic regions in vivo (Table 1; Collo et al., 1997), suggesting a role for P2X$_7$Rs in the mechanisms of cellular damage induced by hypoxia/ischemia. Up-regulation of the P2Y$_2$R subtype also has been found with stress and injury (Seye et al., 2002; Koshiba et al., 1997 and Turner et al., 1997). For example, P2Y$_2$R up-regulation is induced by a collar placed around a rabbit carotid artery (Seye et al., 2002) and arterial P2Y$_2$R up-regulation is associated with enhanced neointimal hyperplasia, macrophage infiltration and osteopontin
expression in response to UTP (Seye et al., 1997, 2003, 2004 & 2006). These findings indicate for the first time a role for the P2Y\(_2\)R, in development of intimal hyperplasia associated with atherosclerosis and restenosis (Seye et al., 2002; Appendix-1). In Chapter 4, the expression of P2Y\(_2\) receptors was identified in normal adult rodent brains and the relationship of P2Y\(_2\) receptor expression to ischemia-induced injury was determined in a gerbil transient ischemia model (Weisman et al., 2005; Chapter 4).

**Outline of the dissertation**

This dissertation contains five parts concerning the *Regulation and Function of P2Y\(_2\) and P2X\(_7\) Nucleotide Receptors in the Central Nervous System* from (i.e., Chapters 2-4 and the Appendix).

In Chapter 2, we examined P2X\(_7\)-R-mediated apoptosis in rat primary cortical neurons (rPCNs). P2X\(_7\)Rs were functionally expressed in the rPCNs and their activation by extracellular nucleotides was shown to cause apoptotic cell death through an intrinsic JNK1- and ERK-dependent caspase-8/9/3 activation pathway.

Chapter 3 extends the examination of nucleotide receptors in rPCNs to the P2Y\(_2\) receptor subtype. P2Y\(_2\)R mRNA and receptor activity were virtually absent in unstimulated rPCNs but was dramatically up-regulated upon overnight treatment with IL-1\(\beta\). Furthermore, activation of P2Y\(_2\)R in rPCNs enhanced the release of sAPP\(\alpha\), a putative neuroprotective secretory amyloid protein, by an ADAM10/17- and PI3K/ERK-dependent mechanism.

In Chapter 4, the expression pattern of P2Y\(_2\) receptor was studied in adult rodent
brain slices. Moreover, the effect of ischemia on the expression level of P2Y$_2$Rs in the rodent brain was analyzed by *in situ* hybridization and RT-PCR in a gerbil transient global ischemia model.

This dissertation concludes with Chapter 5, which addresses future directions and the scientific significance of the completed research followed by an Appendix that presents data from other projects undertaken.

CHAPTER 2

P2X7 NUCLEOTIDE RECEPTORS MEDIATE CASPASE-8/9/3-DEPENDENT APOPTOSIS IN RAT PRIMARY CORTICAL NEURONS

Kong, Q. et al., (2005) Purinergic Signalling 1:337-347
ABSTRACT

Apoptosis is a major cause of cell death in the nervous system. It plays a role in embryonic and early postnatal brain development and contributes to the pathology of neurodegenerative diseases. Here, we report that activation of the P2X$_7$ nucleotide receptor (P2X$_7$-R) in rat primary cortical neurons (rPCNs) causes biochemical (i.e., caspase activation) and morphological (i.e., nuclear condensation and DNA fragmentation) changes characteristic of apoptotic cell death. Caspase-3 activation and DNA fragmentation in rPCNs induced by the P2X$_7$-R agonist BzATP were inhibited by the P2X$_7$-R antagonist oxidized ATP (oATP) or by pretreatment of cells with P2X$_7$-R antisense oligonucleotide indicating a direct involvement of the P2X$_7$-R in nucleotide-induced neuronal cell death. Moreover, Z-DEVD-FMK, a specific and irreversible cell permeable inhibitor of caspase-3, prevented BzATP-induced apoptosis in rPCNs. In addition, a specific caspase-8 inhibitor, Ac-IETD-CHO, significantly attenuated BzATP-induced caspase-9 and caspase-3 activation, suggesting that P2X$_7$-R-mediated apoptosis in rPCNs occurs primarily through an intrinsic caspase-8/9/3 activation pathway. BzATP also induced the activation of JNK1 and ERK1/2 in rPCNs, and pharmacological inhibition of either JNK1 or ERK1/2 significantly reduced caspase activation by BzATP. Taken together, these data indicate that extracellular nucleotides mediate neuronal apoptosis through activation of P2X$_7$-Rs and their downstream signaling pathways involving JNK1, ERK and caspases 8/9/3.
INTRODUCTION

ATP is an important extracellular messenger generated from various sources including release from presynaptic vesicles upon nerve stimulation in the peripheral and central nervous systems (Burnstock et al., 1978). Extracellular ATP functions as a neuromodulator by activation of cell surface P2 nucleotide receptors that are widely expressed in the nervous system (Burnstock 1980; Inoue 2002). Based on their distinct structure, P2 nucleotide receptors are classified into two families: G protein-coupled P2Y receptors (P2YR_{1, 2, 4, 6, 11-14}; Abbracchio et al., 2003) and ligand-gated ion channels (P2XR_{1,7}; Burnstock 2000). Functional responses to activation of these P2 receptor subtypes in cells of the nervous system under normal and pathological conditions include cell apoptosis, proliferation and migration, inflammation, ion transport, and neurotransmission (Burnstock 2000; Norenberg & Illes 2000; von Kugelgen & Wetter 2000; Khakh 2001 and Illes et al., 2004). Therefore, P2 receptors in the nervous system may prove to be useful pharmaceutical targets in the treatment of neurological disorders.

The seven subtypes of the ionotropic ATP-gated P2XR family, ranging from 379 to 595 amino acids in length, regulate the intracellular calcium concentration through ligand-stimulated increases in the cell membrane permeability to extracellular Ca^{2+} ions (Benham 1990; Di Virgilio et al., 2001a). In contrast to other P2XRs, the P2X_{7}R subtype functions exclusively as a homomeric receptor (Chessell et al., 1998; North & Surprenant 2000). The P2X_{7}R is a 595-amino acid polypeptide containing two membrane-spanning domains, a large extracellular loop, and intracellular N- and
C-terminal domains including a C-terminal tail that is the longest among the cloned P2XRs (Surprenant et al., 1996; Rassendren et al., 1997). P2X7Rs have been reported in microglial cells (Collo et al., 1997) where they play a role in cytokine release (Ferrari et al., 1997). These receptors are also found in cultured astrocytes and Schwann cells (Duan et al., 2003; Grafe et al., 1999), spinal cord neurons and in other regions of the central nervous system (Deuchars et al., 2001; Atkinson et al., 2004).

Brief stimulation of the P2X7R with ATP results in formation of a non-selective cationic channel that promotes the influx of Ca$^{2+}$ and the equilibration of the transmembrane sodium and potassium gradients leading to membrane depolarization (Surprenant et al., 1996; Rassendren et al., 1997; Weisman et al., 1984; Virginio et al., 1999). Subsequent responses to P2X7R activation include the formation of a nonselective pore for molecules up to 900 Da (Weisman et al., 1984; Virginio et al., 1999), extensive membrane blebbing, and eventual cell death (Virginio et al., 1999).

Activation of the P2X7R was reported to elicit Ca$^{2+}$ influx in cerebrocortical nerve terminals (Lundy et al., 2002) and hippocampal glutamate release (Sperlagh et al., 2002), which has been confirmed by studies with P2X7R knockout mice (Papp et al., 2004). In an ex vivo model of organotypic hippocampal cultures, P2X7R activation was shown to directly participate in cell damage induced by oxygen/glucose deprivation (Cavaliere et al., 2004). It has been shown that a Pro-451 to Leu polymorphism within the C-terminal tail of the P2X7R interferes with the ability of the receptor to induce cell death in murine thymocytes (Le Stunff et al., 2004). The P2X7R also has been shown to mediate ATP-induced cell death in human embryonic
kidney cells (Wen et al., 2003) and human cervical epithelial cells (Wang et al., 2004). A recent study demonstrated that spinal cord injury was associated with prolonged P2X$_7$R activation of spinal cord neurons by extracellular ATP, which resulted in high-frequency spiking, increases in cytosolic calcium levels and neuronal degeneration, responses that were reversed by P2X$_7$R inhibition (Wang et al., 2004).

In the present study, we demonstrate that the P2X$_7$R agonists BzATP or ATP induce nuclear condensation and DNA fragmentation in rat primary cortical neurons (rPCNs). These apoptotic responses in rPCNs were dependent on the functional expression of P2X$_7$Rs that mediate the ERK1/2- and JNK1-dependent activation of caspases-8/9/3.

**MATERIALS AND METHODS**

*Materials*

Fetal bovine serum (FBS) was obtained from Hyclone (Logan, UT, USA). Dulbecco’s Modified Eagle’s Medium (DMEM), Minimum Essential Medium (MEM), Neurobasal Medium, penicillin (100 units/ml), streptomycin (100 units/ml) and B27-AO (B27 without cortex antioxidants) were obtained from Gibco-BRL (Carlsbad, CA, USA). Rabbit anti-rat ERK1/2, horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG, and HRP-conjugated goat anti-mouse IgG antibodies were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Goat anti-rat P2X$_7$R antibody was obtained from Alomone (Jerusalem, Israel). Rabbit anti-rat caspase-8 antibody was obtained from Biovision Inc. (Mountain View, CA,
USA). Mouse anti-NeuN antibody was obtained from Chemicon International Inc. (Temecula, CA, USA). Alexa Fluor TM 488 goat anti-mouse IgG antibody, Alexa Fluor TM 594 goat anti-rabbit IgG antibody, YO-PRO-1, TO-PRO-3 and the Prolong anti-fade kit were obtained from Molecular Probes Inc. (Eugene, OR, USA). All other antibodies were obtained from Cell Signaling Technology (Beverly, MA, USA). Caspase-3 and caspase-9 inhibitors were obtained from R&D (Minneapolis, MN, USA). Caspase-8 inhibitor was obtained from BioSource International Inc. (Camarillo, CA, USA). The Precision Plus Protein Standards and nitrocellulose membranes (0.45 mm) were obtained from Bio-Rad (Hercules, CA, USA). LumiGLO chemiluminescent substrates were obtained from New England Biolabs (Beverly, MA, USA). The RNeasy Mini Kit was obtained from Qiagen (Chatsworth, CA, USA). The Apoptotic DNA-ladder kit, the First Strand cDNA Synthesis kit and the TUNEL In Situ Cell Death Detection kit were obtained from Roche (Indianapolis, IN, USA). Nucleotides and all other biochemicals were obtained from Sigma Chemical Co. (St. Louis, MO, USA).

Primary cell culture of cortical neurons

Experimental procedures for cell culture of rat primary cortical neurons (rPCNs) were carried out essentially as described by Suen et al. (Suen et al., 2003). Briefly, cerebral cortices from 18-day-old embryos of Sprague-Dawley rats were removed and the meninges discarded. The brain tissue was mechanically dissociated in HGGMEM comprised of 1.78 g glucose, 100 IU/ml penicillin, 100 μg/ml streptomycin, 7.5 μg/ml fungizone, 2 mM glutamine in 88 ml of MEM and 10% (v/v) horse serum. The tissue
clumps were dispersed with a 10 ml pipette and suspended in 6 ml of 0.25% (w/v) trypsin at 37 °C for 10 min. After incubation, 2 ml of heat-inactivated horse serum were added to block trypsin activity. Cells were centrifuged at 4000 g for 5 min and the pellet was suspended in HGGMEM with 10% horse serum. The cell suspension was filtered through a sterilized 75 mm cell strainer (nylon membrane; Becton Dickinson, Franklin Lakes, NJ) and cells were counted and seeded into plastic culture plates that were precoated with poly-D-lysine (0.1 μg/ml). After 16 h and every 3 days thereafter, the medium was replaced with B27-AO Neurobasal Medium (2 mM glutamine, 8.9 g glucose, 100 IU/ml penicillin, 100 μg/ml streptomycin, 7.5 μg/ml fungizone, 10 ml of B27 minus AO, and Neurobasal Medium (Gibco-BRL) to 500 ml) and the neurons were ready for use after 7 days in culture.

**RT-PCR analysis of P2XR mRNA expression**

Total RNA was isolated from rPCNs using the RNeasy Mini Kit (Qiagen). cDNA was synthesized from the purified RNA using the First Strand cDNA Synthesis Kit for RT-PCR (AMV) (Roche). Five percent of the synthesized cDNA was used as a template in PCR reactions with the Expand High Fidelity PCR System (Roche). Specific oligonucleotide primers were designed to selectively amplify cDNA for individual P2XR subtypes, as shown in Table 2. The amplification was performed using 35 cycles of denaturation at 95 °C for 30 s, with annealing at 60 °C for 30 s and extension at 72 °C for 1 min. The resulting PCR products were resolved on a 1% (w/v) agarose gel containing 10 mg/ml ethidium bromide and photographed under UV illumination.
**Single cell calcium assay**

The $[Ca^{2+}]_i$ was quantified in single cells with the $Ca^{2+}$-sensitive fluorescent dye fura-2, using an InCyt Dual-Wavelength Fluorescence Imaging System (Intracellular Imaging, Cincinnati, OH). Rat PCNs cultured on a poly-D-lysine-coated coverslip were incubated with 2.5 μM fura-2-acetoxymethylester at 37 °C for 30 min in physiological salt solution (PSS) containing (mM) NaCl 138, KCl 5, CaCl$_2$ 2, MgCl$_2$ 1, HEPES 10, glucose 10, pH 7.4, and washed with PSS. The coverslip with fura-2-loaded cells was positioned on the stage of an inverted epifluorescence microscope (Nikon; model TMD) and stimulated with agonists at 37 °C, as described in the figure legends. Cells were exposed to 340/380 nm light and fluorescence emission at 505 nm was converted to $[Ca^{2+}]_i$ using a standard curve created with solutions containing known concentrations of $Ca^{2+}$. Increases in $[Ca^{2+}]_i$ were measured by subtracting basal $[Ca^{2+}]_i$ from the maximum agonist-induced increase in $[Ca^{2+}]_i$. The percentage of cells that responded to ATP/BzATP was also determined. Viable cells were identified by responsiveness to carbachol and non-responding cells were eliminated.

**Detection of nuclear condensation**

Rat PCNs were cultured in B27-AO Neurobasal medium on poly-D-lysine-coated coverslips in 12-well plates until 50-70% confluence. After nucleotide treatments, medium was removed and cells were washed once and incubated with DAPI-methanol staining solution (1 mg/ml) for 15 min at 37 °C. The staining solution was removed and the cells were washed with methanol. The inverted coverslip was
placed onto a microscope slide using glycerol as the mounting agent. Nuclear morphology was observed under a fluorescence microscope (Nikon, Eclipse TE300) with a 340/380 nm excitation filter and a LP 430 nm barrier filter. DAPI has an absorbance maximum at 340 nm and an emission maximum at 488 nm in aqueous solution (Kapus’cin’ski et al., 1978).

**DNA laddering assay**

Rat PCNs were cultured in B27-AO Neurobasal medium in 100 mm dishes to 70% confluence, and incubated in serum-free medium overnight with or without BzATP, or treated for 2 h with 500 μM H2O2 and DNA was isolated using the Apoptotic DNA-ladder kit (Roche, Indianapolis, IN) according to the manufacturer’s instructions. DNA also was isolated from lyophilized apoptotic U937 cell lysate (provided with the DNA-ladder assay kit) for use as a positive control. Briefly, the medium was replaced with 200 μl of PBS and 200 μl of binding buffer (6 M guanidine-HCl, 10 mM urea, 10 mM Tris-HCl, pH 4.4, 20% (v/v) Triton X-100). After 10 min at 15-25 °C, 100 ml of isopropanol were added and the samples were transferred to a filter tube and centrifuged for 1 min at 10,000 g (Spectrafuge Labnet, Edison, NJ). The fluid in the collection tube was discarded and the upper filter column was washed with 500 μl of washing buffer (20 mM NaCl and 2 mM Tris-HCl, pH 7.5, 40% (v/v) ethanol) followed by centrifugation twice for 1 min at 13,000 g. After the residual washing buffer was removed, the DNA was eluted with 200 μl of pre-warmed (70 °C) elution buffer (10 mM Tris, pH 8.5). The concentration and purity of the eluted DNA was determined by measuring the optical density at 260 and
280 nm. DNA was electrophoresed in a 2% (w/v) agarose gel at 80 V for 1 h in TBE buffer (89 mM Tris base, 89 mM boric acid, 2 mM EDTANa₂-salt, pH 8.3) and visualized under UV light.

*TUNEL assay*

After treatment with nucleotides or H₂O₂, rPCNs were fixed with fresh 4% (v/v) paraformaldehyde in PBS and treated with 3% (v/v) H₂O₂ in methanol to inhibit endogenous peroxidase activity. Then, DNA strand breaks in fixed cells were detected with a TUNEL *In Situ* Cell Death Detection kit (Roche) according to the manufacturer’s instructions. The number of TUNEL-positive cells and the total cell number were determined by fluorescence (Nikon; Eclipse TE300) using an excitation wavelength in the range of 450-500 nm and a detection wavelength in the range of 515-565 nm (green) and light microscopy with cell counting, respectively, at 200x magnification.

*Application of P2X₇ antisense oligonucleotide*

Antisense oligonucleotide treatment was performed as previously described (Seye *et al*., 2002). Phosphorothioate-modified oligonucleotides to rat P2X₇ were synthesized and purified by Integrated DNA Technologies (ADT, Coralville, IA, USA). Sequences were designed as follows: sense 5’-AGAGCGTGAATTACGGCATAAA-3’, antisense 5’-TTGATGGTGCCGTAATTCACGCTCT-3’. Sequences were checked for uniqueness with the National Center for Biotechnology Information’s Basic Local Alignment Search Tool (http://www.ncbi.nlm.nih.gov/BLAST). The rPCNs were incubated with 0.1 or 1 μmol/L P2X₇ sense or
antisense S-oligonucleotide for 6 h in serum-free medium containing 1.4% (v/v) DOTAP liposomal reagent (Roche Diagnostics). Fresh serum-free medium was added with or without BzATP, and cells were cultured for an additional 18 h.

**Western blot analysis**

Rat PCNs cultured in 6-well plates were treated with 300 μM BzATP in the presence or absence of inhibitors as indicated. The cells were washed twice with ice-cold PBS, and lysed for 5 min in 200 ml of ice-cold lysis buffer (20 mM Tris-HCl, pH 7.5, 2% (w/v) sodium dodecyl sulfate (SDS), and 1 mM sodium orthovanadate). Lysate (30 mg of protein) was added to Laemmli sample buffer (187.5 mM Tris-HCl, pH 6.8, 6% (w/v) SDS, 1.8% (v/v) β-mercaptoethanol and 0.003% (w/v) bromophenol blue). Samples were heated for 5 min at 96-100 °C, and subjected to 7.5% (w/v) SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to nitrocellulose membranes for protein immunoblotting. After overnight blocking at 4 °C with 5% (w/v) fat-free milk in TBS-T (10 mM Tris-HCl, pH 7.4, 120 mM NaCl, and 0.1% (v/v) Tween-20), membranes were incubated with either 1:1000 dilution of anti-ERK1/2, anti-phospho-ERK1/2, anti-phospho-JNK, or anti-P2X7R antibodies for 2 h at room temperature, or 1:1000 dilution of anti-cleaved caspase-3, anti-caspase-3, anti-cleaved caspase-9, anti-caspase-9, or anti-caspase-8 antibodies overnight at 4 °C followed by incubation with HRP-conjugated anti-rabbit or anti-mouse IgG antibodies (1:1000 dilution in TBS-T containing 5% (w/v) fat-free milk) for 1 h at room temperature. For normalization of protein loading, the membranes were stripped of antibodies by incubation for 30 min at 60 °C in stripping buffer (62.5 mM Tris-HCl,
pH 6.8, 100 mM 2-mercaptoethanol, and 2% (w/v) SDS), and re-probed with 1:2000 dilution of rabbit polyclonal anti-actin antibody (2 h at room temperature; Cytoskeleton, Denver, CO) followed by 1:2000 dilution of HRP-conjugated anti-rabbit IgG antibody (1 h at room temperature). Protein immunoreactivity was visualized on autoradiographic film using the LumiGlo Chemiluminescence System (New England BioLabs), according to the manufacturer’s instructions. The protein bands detected on X-ray film were quantified using a computer-driven scanner and Quantity One software (Bio-Rad, Hercules, CA). The activation levels of kinases or caspases were calculated as a percentage of control (i.e., total kinase, caspase, or actin).

**Immunofluorescence**

After fixation and permeabilization, rPCNs cultured on coverslips in 6-well plates were incubated in 2.5% (w/v) BSA and 2.5% (v/v) goat serum in PBS for 1 h at room temperature followed by incubation overnight with mouse anti-NeuN antibody (1:100 dilution; Chemicon) and rabbit anti-cleaved caspase-3 antibody (1:100 dilution; Cell Signaling) in 0.25% BSA and 0.25% goat serum in PBS. Cells were washed three times with PBS and then incubated with 1:200 dilution of goat anti-mouse Alexa Fluor 488- or goat anti-rabbit Alexa Fluor 594-conjugated IgG antibody (Molecular Probes, Eugene, OR) in 0.25% BSA and 0.25% goat serum in PBS for 1 h at 37 °C. Nuclei were stained with TO-PRO-3 (Molecular Probes), cells were rinsed with PBS and mounted on glass slides in ProLong antifade reagent (Molecular Probes). Images were obtained on a Bio-Rad MRC 1024 laser scanning confocal imaging system.
coupled to an Olympus IX70 inverted microscope. The imaging system was controlled by Laser Sharp software (version 3.2; Bio-Rad, Hercules, CA). Alexa 488-labeled slices were excited by 488 nm laser light, and images were acquired with a 522 nm emission filter with a bandwidth of 35 nm, whereas Alexa 594-labeled slices were excited by 568 nm light and images acquired with a 585 nm longpass emission filter. Settings of the confocal microscope were optimized for imaging in an initial experiment and then equivalently applied to all sections. Laser power and photomultiplier tube (PMT) gain were adjusted to ensure that even the brightest fluorescence was below saturation levels. Neurons were randomly chosen and scanned at 512 x 512 pixel resolution.

Statistical analysis

Results are expressed as the means ± S.E.M. Statistical analysis of data was performed using Graph Pad Prism version 4.0. Statistical significance was determined by student t-test. Differences were considered statistically significant when p < 0.05.

RESULTS

Purity of rat cortical neurons in primary culture

The purity of rPCNs was determined by monitoring morphology with phase contrast microscopy and by immunofluorescence assay with the neuron-specific marker NeuN and the nuclear stain, TO-PRO-3 (Figure 1A). NeuN staining was found primarily in the nucleus of the neurons with lighter staining in the cytoplasm. About 95% of the cells were determined to be cortical neurons based on the ratio of NeuN
positive cells to total cells counted by TO-PRO nuclear staining (data not shown).

Functional P2X7Rs are expressed in rat PCNs

Rat PCNs express P2X7R mRNA, as well as mRNAs for P2X2, P2X3, P2X5, and P2X6 receptors (Figure 1B). Furthermore, immunoblot analysis indicated that rPCNs express P2X7R protein (Figure 1C). The P2X7R agonists ATP and BzATP (Erb et al., 1990) caused a dose-dependent increase in [Ca^{2+}]_i in rPCNs (Figure 2), suggesting that calcium influx is stimulated by activation of the endogenously expressed P2X7R protein. Calcium responses were also observed by stimulation of rPCNs with 2-methylthio-ADP (data not shown), an agonist of the P2Y1R, indicating that other P2R subtypes besides the P2X7R can regulate increases in [Ca^{2+}]_i.

ATP and BzATP induce nuclear condensation and DNA fragmentation in rPCNs

Treatment of rPCNs with either BzATP (300 µM) or ATP (100 µM) overnight caused nuclear condensation as indicated by increased DAPI staining of nuclei (Figure 3). BzATP-induced nuclear condensation was inhibited by the P2X7R antagonist oATP, consistent with the involvement of P2X7Rs in this process. Moreover, BzATP treatment of rPCNs caused DNA fragmentation, suggestive of apoptotic cell death (Figure 4). BzATP or ATP also caused DNA strand breakage in rPCNs, another indicator of apoptosis, detected as an increase in the number of TUNEL-positive cells (Figure 5). These data suggest that BzATP or ATP can cause apoptosis in rPCNs through a pathway involving P2X7R activation.

P2X7R-mediated caspase-3 and caspase-9 activation
Caspase-3 is an essential component of apoptotic pathways in many cell types, including neurons (Salvesen and Dixit, 1997), and is activated by the sequential release of cytochrome c from mitochondria and the activation of caspase-9 (Li et al., 1997). Consistent with a role for caspase-3 in nucleotide-induced neuronal apoptosis, nuclear condensation caused by BzATP was diminished by treatment of rPCNs with the caspase-3 inhibitor Z-Asp(OMe)-Glu(OMe)-Val-Asp(OMe)-FMK (Z-DEVDFMK; Figure 3C). Results also indicated that treatment of rPCNs with either ATP or BzATP significantly increased the cleavage of caspase-3 in a time- and dose-dependent manner (Figure 6A). BzATP-induced caspase-3 cleavage was inhibited by oATP (Figure 6B), the caspase-3 inhibitor Z-DEVD-FMK (Figure 6B), or P2X₇ antisense oligonucleotide (Figure 6C). Although recent studies indicate that oATP might act independently from P2 receptor inhibition (Beigi et al., 2003), inhibition of BzATP-induced caspase-3 cleavage by P2X₇ antisense oligonucleotide confirms the involvement of the P2X₇R. Since no preparation of primary neurons is devoid of glial cells, dual immunofluorescence analysis for neuron-specific NeuN and cleaved caspase-3 was performed to evaluate whether the apoptotic cells were neurons. The majority of cells treated with BzATP were positive for cleaved caspase-3 and NeuN (e.g., pink and white arrows in Figure 6D), indicating that a large percentage of cells undergoing apoptosis were neurons. NeuN immunoreactivity has been reported to decrease under several pathological conditions (Unal-Cevik et al., 2004), and therefore NeuN detection may decrease with caspase-3 activation in apoptotic neurons, suggesting that some apoptotic neurons may go undetected. BzATP also caused the
cleavage of caspase-9 (Figure 7A), whereas activation of caspase-9 and caspase-3 were significantly inhibited by the caspase-8 inhibitor Ac-IETD-CHO (Figure 7B) or the caspase-9 inhibitor Z-LEHD-FMK (data not shown), indicating that caspase-8 also plays a role in activating downstream caspase family members (e.g., caspase-9/3) of the P2X$_7$R-mediated apoptosis pathway. We also detected an inhibitory effect of the caspase-9 inhibitor, Z-LEHD-FMK, on caspase-8 cleavage (Figure 7C) suggesting that caspase-8 and caspase-9 may regulate caspase-3 activity in a non-linear fashion.

*Caspease-3 activation by BzATP in rPCNs is dependent upon ERK1/2 and JNK1 phosphorylation*

P2X$_7$R-mediated activation of extracellular signal-regulated kinases (ERK1/2) in rat primary astrocytes (Panenka et al., 2001) and SAPK/JNK in human and rodent macrophages occur independently of the activation of caspase-1- or caspase-3-like proteases (Humphreys et al., 2000). Here, we tested whether ERK1/2 or JNK1 activities were involved in BzATP-induced apoptosis in rPCNs. As indicated in Figure 8, both ERK1/2 and JNK1 were rapidly phosphorylated in response to BzATP or ATP in a dose- and time-dependent manner. Inhibition of ERK1/2 or JNK1 phosphorylation in rPCNs with either the MEK inhibitor UO126 or the JNK inhibitor SP600125, respectively, attenuated caspase-3 activation, indicating the involvement of ERK1/2 and JNK1 in BzATP-induced neuronal cell death (Figure 9).

**DISCUSSION**

The results obtained with rat PCNs indicate that activation of the P2X$_7$R by its
agonists BzATP or ATP promotes the cleavage of caspases-8/9/3 and the appearance of cellular markers indicative of apoptosis including DNA degradation and nuclear condensation and fragmentation. Since BzATP can activate other P2X receptor subtypes, albeit at higher concentrations than the P2X7R (Bianchi et al., 1999), we explored the role of the P2X7R in the apoptotic effects of BzATP in rPCNs using P2X7 antisense oligonucleotide to downregulate P2X7R expression and the P2X7R antagonist oATP. Results indicate that inhibition of P2X7R activity significantly inhibited BzATP-induced nuclear condensation (by P2X7R antagonist oATP; Figure 3) and caspase-3 cleavage (by both oATP and P2X7R antisense oligonucleotide; Figure 6), apoptotic responses that were diminished by incubation of rPCNs with the caspase-3 inhibitor, Z-DEVD-FMK (Figures 3C and 6B). These data strongly suggest that P2X7Rs mediate BzATP-induced apoptosis in rPCNs, although this does not rule out a potential role for other P2 nucleotide receptors.

P2X7-R-mediated neuronal apoptosis in vivo requires that ATP be released from neurons or non-neuronal cells to activate cell surface receptors on neighboring neurons. Neuronal P2X7 receptors are targeted to presynaptic terminals in the central and peripheral nervous systems and activation of the P2X7R has been indicated to promote release of vesicular contents from presynaptic terminals (Deuchars et al., 2001). ATP is present at high concentrations in synaptic vesicles and is released as a co-transmitter with noradrenaline, acetylcholine and other neurotransmitters (Burnstock et al., 1978). ATP release also has been demonstrated in a model of spinal cord injury (Sim et al., 2004). Thus, ATP release from excited neurons or damaged
cells is an assumed consequence of any brain injury or disease (e.g., ischemia, spinal cord injury, or neurodegenerative diseases), suggesting that pro-apoptotic P2X₇Rs are likely activated under pathological conditions in vivo. Recent research indicates a lack of P2X₇R expression in adult rat hippocampal neurons (Khera et al., 2004), whereas our studies demonstrate functional P2X₇R expression in rPCNs from 18-day old embryos. We have detected P2X₇R mRNA in freshly isolated rPCNs (data not shown) and 7-10 day-old cultures (Figure 1), suggesting that the in vitro cell culture procedure alone was not required for P2X₇R expression.

Caspase activation is known to play a central role in the execution of apoptosis by causing nuclear condensation, DNA fragmentation and other apoptotic changes. In the mitochondrial-initiated pathway of apoptosis, caspase activation is triggered by the formation of a multimeric Apaf-1/cytochrome c complex that is fully functional in recruiting and activating procaspase-9 (Li et al., 1997). Activated caspase-9 will then cleave and activate downstream caspases such as caspase-3, -6, and -7. In rPCNs, it was not surprising that activation of caspase-3 was significantly inhibited by the caspase-9 inhibitor Z-LEHD-FMK (data not shown), since caspase-9 is known to activate caspase-3. We also found that in rat PCNs, the caspase-8 inhibitor Ac-IETD-CHO partially inhibited caspase-9 and caspase-3 activation (Figure 7B) indicating that caspase-8 cleavage may be an early event in this neuronal apoptosis pathway. Caspase-8 has been reported to play a role in cytochrome c-dependent apoptosis (Viswanath et al., 2001) and caspase-8 activation is associated with Fas receptor-induced apoptosis (Zhuang et al., 1999) and can result in the cleavage and
activation of Bid, a proapoptotic member of the Bcl-2 family (Li et al., 1998). Truncated Bid translocates from the cytoplasm to the mitochondria, where it appears to antagonize the actions of anti-apoptotic Bcl-2, thereby causing an efflux of cytochrome c from the mitochondria and downstream caspase-9/3 activation (Li et al., 1998; Kuwana et al., 1998; Luo et al., 1998; Schendel et al., 1999; Wei et al., 2001).

In human embryonic kidney HEK-293 cells expressing P2X7Rs, extracellular ATP induced apoptosis associated with activation of poly (ADP-ribose) polymerase (PARP) and a decrease in Bax protein expression (Wen et al., 2003). We examined the effect of ATP/BzATP on the expression of Bcl-2 family members in rPCNs but failed to detect a significant change in Bax and Bcl-2 protein expression (data not shown). Evidence from cell-free and in vitro expression systems has indicated that caspase-3 can induce cleavage and activation of the upstream initiator caspase-8 (Slee et al., 1999; Wolf and Green, 1999; Tang et al., 2000). Our data indicated that inhibition of caspase-9 cleavage decreased caspase-8 cleavage (Figure 7C), consistent with the ability of downstream caspases to regulate the cleavage of initiator caspases.

We have demonstrated that activation of P2X7Rs in rPCNs increases calcium influx (Figure 2) and stimulates phosphorylation of the intracellular kinases ERK1/2 and JNK1 (Figure 8). Furthermore, inhibition of ERK1/2 or JNK1 phosphorylation decreased BzATP-induced caspase-3 cleavage (Figure 9). Our previous studies demonstrating that P2X7R-mediated ERK1/2 activation was dependent on extracellular Ca^{2+} (Gendron et al., 2003) suggest a similar role for BzATP-stimulated calcium influx in rPCNs (Figure 2). Recent studies indicate that activation of ERK
and phosphatidylinositol 3-kinase/Akt signaling pathways caused inhibition of caspase-3 and cell apoptosis (Khreiss et al., 2002). It also has been reported that inhibition of MEK/ERK signaling is required for the induction of apoptosis by Sulindac metabolites (Rice et al., 2004). Nonetheless, our data support the hypothesis that ERK1/2 and JNK1 activation can promote P2X7R-mediated apoptosis in rPCNs, although the mechanism involved requires further investigation. P2X7Rs can promote neuronal cell death by mediating the release of glutamate and inflammatory factors from cortical neurons, RAW 264.7 macrophages, and astrocytes (Duan et al., 2003; Hu et al., 1998; Guerra et al., 2003). Moreover, glutamate can induce ATP release from astrocytes (Queiroz et al., 1999), suggesting that ATP and glutamate have reciprocal roles that contribute to the propagation of an apoptotic signal. It also has been reported that the P2X7R modulates macrophage production of TNF-α, IL-1β and nitric oxide (NO) following LPS exposure (Hu et al., 1998), consistent with a role for the P2X7R in inflammation (Di Virgilio et al., 2001b). In addition to these factors, structural features within the P2X7R indicate that the mechanism whereby it regulates apoptosis is likely to be complex. There are several functional domains located in the P2X7R C-terminal tail including an LPS-binding domain, a SH3-binding domain, and an overlapping Fcelldeath domain, which appear to be important for receptor trafficking and various physiological functions (Denlinger et al., 2001), and the role of these domains in P2X7R-mediated apoptosis of neurons warrants further investigation. Our studies with the membrane impermeant fluorescent dye YO-PRO-1 (molecular weight: 375 Da) indicate that BzATP causes pore formation (YO-PRO-1
uptake) in rPCNs (data not shown), consistent with the report that apoptosis in the retinal microvasculature is associated with P2X7 receptor-mediated pore formation (Sugiyama et al., 2004).

A recent study indicated that spinal cord neurons expressed an abundance of P2X7Rs, and exposure of freshly prepared spinal cord slices to ATP or BzATP evoked high frequency firing and irreversible increases in the cytosolic Ca2+ concentration (Wang et al., 2004). Significant cell death occurred 24 h after spinal cord injury in areas of high ATP release surrounding the epicenter of the injury, while local injection of oATP in the peritraumatic zone strongly reduced both apoptotic cell number and the severity of histological injury, suggesting the involvement of a P2X7R. Other studies indicate that the P2X7R is up-regulated in a mouse model of Alzheimer’s disease (Parvathenani et al., 2003). Thus, the P2X7R may represent a promising therapeutic target to inhibit neurodegeneration due to injury or disease.

In summary, the data presented indicate that BzATP and ATP can stimulate P2X7Rs in embryonic rat primary cortical neurons leading to the activation of the caspases-8/9/3 and the induction of DNA degradation and nuclear condensation and fragmentation, apoptotic responses that appear to be regulated by ERK1/2 and JNK1. Since neuronal apoptosis occurs in Alzheimer’s disease, Parkinson’s disease and other neurodegenerative disorders, a better understanding of the mechanisms of P2X7R-mediated apoptosis may lead to novel therapies to prevent apoptosis-related brain injuries.

Figure 1. Purity of rat primary cortical neurons (rPCNs) and P2X$_7$R expression.

(A) Rat PCNs were cultured on coverslips in 6-well plates and neurons were labeled with mouse NeuN monoclonal antibody (Panel a) and cell nuclei with TO-PRO-3 (Panel b); merged picture shown in Panel c. (B) RNA was isolated from rPCNs maintained in culture for 7-10 days and RT-PCR was used to amplify mRNAs to P2X$_{1-7}$Rs, as described in the “Materials and Methods”. The amplified PCR products were resolved by gel electrophoresis, and data shown are representative of results from three independent experiments. Results are shown of PCRs performed in the presence (+) or absence (-) of reverse transcriptase (RT). G3PDH primers were used to amplify G3PDH mRNA as a positive control. (C) P2X$_7$R protein expression was detected by Western blot analysis, as described in the “Materials and Methods”. Human 1321N1 cells expressing the recombinant human P2X$_7$R or the empty expression vector pLXSN were used as positive (+) or negative (-) controls, respectively. Precision Plus Protein Standards are indicated as ‘75KD’ and ‘100KD’.
Figure 2. ATP- and BzATP-induced increases in \([\text{Ca}^{2+}]_i\) in rat PCNs. (A) Single cell calcium assays were performed on rPCNs that were cultured for 7-10 days on poly-D-lysine-coated coverslips. Cells were incubated in PSS with the indicated concentration of BzATP or ATP and the maximum increase in \([\text{Ca}^{2+}]_i\) was determined, as described in the “Materials and Methods”. (B) The percentage of cells responding to BzATP or ATP is shown as the mean +/- S.E.M. of results from three experiments.
Figure 3. ATP/BzATP-induced nuclear condensation mediated by the P2X7R is dependent on caspase-3 activation. (A) Rat PCNs were cultured for 7-10 days, incubated in serum-free HGGMEM for 6 h and stimulated with BzATP (300 μM) or ATP (100 μM) for 16 h or with H2O2 (1 mM) for 2 h. When indicated, 500 μM oATP was added 2 h prior to addition of BzATP. Cells cultured in B27-AO Neurobasal medium (NB) or in serum-free HGGMEM (-) overnight were used as controls. Then, nuclear condensation was determined by DAPI staining and detected by fluorescence microscopy, as described in the “Materials and Methods”. (B) Cells were treated as in (A) except that the data were expressed as a percentage of cells that exhibited DAPI stained nuclei. Data are the means +/- S.E.M. of results from at least four experiments, where *p < 0.05, and ***p < 0.001 indicate significant differences from the serum-starved control (-), and where ###p < 0.001 indicates a significant difference from BzATP treatment. (C) rPCNs were treated as in (A) except that 10 μM Z-DEVD-FMK, a caspase-3 inhibitor, was added for 1 h prior to BzATP, when indicated.
Figure 4. BzATP stimulates DNA fragmentation in rat PCNs. Rat PCNs were incubated in serum-free HGGMEM for 6 h and then stimulated with BzATP (300 μM) for 16 h or H\textsubscript{2}O\textsubscript{2} (1 mM) for 2 h. Cells cultured in serum-free HGGMEM (−) overnight were used as the control. Then, cells were lysed, total DNA was purified, the DNA concentration was determined, and 3 μg of purified DNA was loaded onto each lane of a 2% (w/v) agarose gel and electrophoresed, as described in the “Materials and Methods”. DNA fragmentation was visualized after electrophoresis of DNA. Apoptotic U937 cells (+++; provided in the Apoptotic DNA-ladder kit) were used as a positive control and “M” indicates the 100 bp DNA ladder marker.
Figure 5. BzATP or ATP induces DNA strand breakage in rat PCNs. Rat PCNs were cultured for 7-10 days, incubated in serum-free HGGMEM for 6 h, and stimulated with BzATP (300 μM) or ATP (100 μM) for 16 h or with H₂O₂ for 2 h. Cells cultured in serum-free HGGMEM (-) overnight were used as the control. Then, cells were fixed and DNA strand breakage was determined by TUNEL assay, as described in the “Materials and Methods”. DNA strand breakage was observed as green fluorescence using fluorescence microscopy.
**Figure 6. P2X₇Rs mediate caspase-3 activation in rat PCNs.** (A) Rat PCNs were incubated in serum-free medium for 6 h and then stimulated with the indicated concentration of ATP or BzATP for 16 h or the time indicated. Cells cultured in B27-AO Neurobasal medium (NB) or in serum-free HGGMEM (-) overnight were used as controls. (B) Cells were treated as in (A) except that 500 μM oATP was added for 2 h or the indicated concentration (1, 10 or 100 μM) of Z-DEVD-FMK was added for 1 h prior to addition of 300 μM BzATP for 16 h. (C) Cells were treated as in (A) except that P2X₇ antisense or sense oligonucleotide was added at the indicated concentration in μg/ml for 8 h prior to addition of 300 μM BzATP for 16 h or 1 mM H₂O₂ for 2 h. Western analysis was performed to determine the relative amounts of caspase-3, cleaved caspase-3 or P2X₇R protein. Data are the means +/- S.E.M. of results from at least three experiments, where *p < 0.05, **p < 0.01, and ***p < 0.001 indicate significant differences from either serum-starved (A) or BzATP-treated (B, C) cells. (D) Rat PCNs were serum-starved overnight in the presence (Panels B, D and F) or absence (Panels A, C, and E) of 300 μM BzATP and then immunofluorescence of the neuron-specific marker NeuN (green; Panels A, B), cleaved caspase-3 (red; Panels C and D), and the nuclear stain TO-PRO (blue; Panels E and F) were detected as described in the “Materials and Methods”. Arrows (pink or white) indicate apoptotic neurons that are both capase-3 and NeuN positive, whereas yellow arrows indicate apoptosis in a NeuN-negative cell. Similar results were obtained in three individually isolated groups of primary cultures.

CHAPTER 3

IL-1β ENHANCES NUCLEOTIDE-INDUCED α-SECRETASE-DEPENDENT
APP PROCESSING IN RAT PRIMARY CORTICAL NEURONS VIA
UPREGULATION OF THE P2Y1 RECEPTOR

Kong, Q. et al., to be submitted
ABSTRACT

The P2Y<sub>2</sub> nucleotide receptor (P2Y<sub>2</sub>R) stimulates α-secretase-dependent cleavage of the amyloid precursor protein (APP) in human 1321N1 astrocytoma cells, causing extracellular release of the neuroprotective protein sAPPα. In this study, we analyzed functional upregulation of the P2Y<sub>2</sub>R by cytokines and the P2Y<sub>2</sub> receptor-mediated production of sAPPα in rat primary cortical neurons (rPCNs). In rPCNs, P2Y<sub>2</sub>R mRNA and receptor activity were virtually absent in unstimulated cells, whereas overnight treatment with the inflammatory cytokine IL-1β upregulated both P2Y<sub>2</sub>R mRNA expression and receptor activity. Furthermore, the P2Y<sub>2</sub>R agonist UTP enhanced the release of sAPPα in rPCNs treated with IL-1β or transfected with P2Y<sub>2</sub>R mRNA. UTP-induced release of sAPPα from rPCNs was completely inhibited by pretreatment of the cells with the metalloproteinase inhibitor TAPI-2 or the PI3K inhibitor LY2904, partially inhibited by the MEK inhibitor U0126, and unaffected by the PKC inhibitor GF109203, suggesting that P2Y<sub>2</sub>R-mediated release of sAPPα from neurons is dependent on ADAM10/17 and PI3K activity, partially dependent on ERK1/2 activity, and does not require activation of PKC. These results suggest that under inflammatory conditions, IL-1β evokes the functional upregulation of the P2Y<sub>2</sub>R in neurons and implicates the activation of the P2Y<sub>2</sub>R in neuroprotection.
INTRODUCTION

Inflammation is established as a central component of several chronic diseases. Various inflammatory mediators, such as cytokines, chemokines, proteases and protease inhibitors, have been detected in the AD brain (Parihar and Hemnani, 2004). Interleukin-1 (IL-1) and tumor necrosis factor α (TNF-α) are rapidly upregulated in a variety of tissues in response to pro-inflammatory stimuli to amplify downstream signaling cascades that mediate inflammation (Cacquevel et al. 2004). In Alzheimer’s disease, IL-1 directly regulates the expression and processing of β-amyloid precursor protein (β-APP), the phosphorylation of tau and the increased production and activity of acetylcholinesterase (AChE) in neurons. These processes result in neuronal stress and injury, which in turn further enhance microglial activation and IL-1 overexpression in a self-propagating cycle. Recent studies, however, indicate that certain aspects of the inflammatory response may have therapeutic potential (Wyss-Coray et al., 2001). Nucleotides co-released with neurotransmitters can activate a widely distributed family of nucleotide receptors in the CNS. P2 nucleotide receptors (i.e., P2X ion channels and G protein-coupled P2Y receptors) have been implicated in the regulation of numerous functions in the mammalian nervous system, including neurotransmission, glial cell migration, cell proliferation, ion transport, neuronal cell apoptosis and survival (Burnstock, 2000; Ciccarelli et al., 2001; Weisman et al., 2005). The P2Y₂ nucleotide receptor is distinguished among other P2 receptors by its ability to be activated equipotently by ATP and UTP and has been shown to be upregulated in response to stress or injury in various cell types, including
activated thymocytes, salivary gland epithelial cells, and models of vascular tissue injury (Koshiba et al., 1997; Turner et al., 1997; Seye et al., 2002). In rat primary cortical astrocytes, the P2Y<sub>2</sub>R is functionally expressed and promotes astrocyte migration through receptor interaction with α<sub>V</sub> integrins, which suggests an important role for P2Y<sub>2</sub>R-mediated signaling pathways in regulating astrogliosis in brain disorders (Wang et al., 2005). However, very little is known about the functional role of the P2Y<sub>2</sub> nucleotide receptor subtype in neurons.

Previously, we demonstrated that the G protein-coupled P2Y<sub>2</sub>R mediates the α-secretase-dependent release of sAPPα from human 1321N1 astrocytoma cells (Camden et al., 2005). Cleavage of APP by α-secretase results in the shedding of nearly the entire ectodomain of APP to yield a large soluble derivative called sAPPα, and essentially precludes the generation of neurotoxic Aβ peptide. Several zinc metalloproteinases, including TNF-α converting enzyme (TACE/ADAM17), ADAM9, ADAM10 and MDC-9, and the aspartyl protease BACE2 can cleave APP at the α-secretase site (Allison et al., 2003). While the proteolytic cleavage of APP is constitutive, it can also be increased by substances such as GPCR agonists that activate protein kinase C (PKC) or other signaling pathways (Nitsch et al., 1997; Kirazov et al., 1997) and may function in the modulation of neuronal excitability, synaptic plasticity, neurite outgrowth, synaptogenesis, and cell survival (Mattson, 1997).
The aim of this study was to determine whether cytokines such as IL-1β regulate functional expression of the P2Y₂R in rat primary cortical neurons and how P2Y₂R signaling pathways affect APP processing in these cells.

MATERIALS AND METHODS

Materials

Fetal bovine serum (FBS) was obtained from Hyclone (Logan, UT). Dulbecco’s Modified Eagle’s Medium (DMEM), Minimum Essential Medium (MEM), Neurobasal Medium, penicillin (100 units/ml), streptomycin (100 units/ml) and B27-AO (B27 without cortex antioxidants) were obtained from Gibco-BRL (Carlsbad, CA). Rabbit anti-rat ERK1/2, horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG, and HRP-conjugated goat anti-mouse IgG antibodies were obtained from Santa Cruz Biotechnology (Santa Cruz, CA). Rabbit anti-rat beta amyloid antibody was obtained from Signet Laboratories (Dedham, MA). All other antibodies were obtained from Cell Signaling Technology (Beverly, MA). The Dual Color Protein Standards and nitrocellulose membranes (0.45 mm) were obtained from Bio-Rad (Hercules, CA). LumiGLO chemiluminescent substrates were obtained from New England Biolabs (Beverly, MA). The RNeasy Mini Kit was obtained from Qiagen (Chatsworth, CA). The First Strand cDNA Synthesis Kit and the PCR Kit were obtained from Roche (Indianapolis, IN). The GenCarrier™2 Transfection Reagent Kit was obtained from Epoch Biolabs (Sugar Land, TX). Nucleotides and all
other biochemicals were obtained from Sigma Chemical Co. (St. Louis, MO).

**Primary cell culture of cortical neurons**

Experimental procedures for cell culture of rat primary cortical neurons (rPCNs) were carried out as previously described (Kong *et al.*, 2005). Briefly, cerebral cortices from 18-day-old embryos of Sprague-Dawley rats were removed and the meninges were discarded. The brain tissue was mechanically dissociated in HGDMEM comprised of DMEM, 10% (v/v) FBS, 2 mM glutamine, 100 IU/ml penicillin, 100 mg/ml streptomycin, and 7.5 mg/ml fungizone. The tissue clumps were dispersed with a 10 ml pipette and suspended in 6 ml of 0.25% (w/v) trypsin at 37 °C for 10 min. Then, 2 ml of heat-inactivated horse serum were added to neutralize trypsin activity. The cell suspension was centrifuged at 900 g for 5 min and the cell pellet was suspended in HGDMEM. The resulting cell suspension was filtered through a sterilized 75 mm cell strainer (Becton Dickinson, Franklin Lakes, NJ) and the cells were seeded into plastic culture plates precoated with poly-D-lysine (0.1 μg/ml). After 16-18 h and every 3 days thereafter, the medium was replaced with B27-AO Neurobasal Medium (2 mM glutamine, 100 IU/ml penicillin, 100 mg/ml streptomycin, 7.5 mg/ml fungizone, 10 ml of B27-AO, and Neurobasal Medium (Gibco-BRL) to 500 ml) and 15 μg/ml 5-fluoro-2’-deoxyuridine was added to retard glial cell proliferation. The neurons were used for experiments after 7 days in culture (DIV7).

**RT-PCR analysis of P2Y<sub>2</sub>R mRNA expression**

Total RNA was isolated from rPCNs using the RNeasy Mini Kit (Qiagen). cDNA was synthesized from the purified RNA using the First Strand cDNA Synthesis Kit
for RT-PCR (AMV; Roche). Five percent of the synthesized cDNA was used as a template in PCR reactions with the Expand High Fidelity PCR System (Roche). Specific oligonucleotide primers were designed to selectively amplify cDNA for P2Y2R and G3PDH, as previously described (Wang et al., 2005). The amplification was performed using 35 cycles for P2Y2R and 30 cycles for G3PDH of denaturation at 95 °C for 30 s, with annealing at 60 °C for 30 s and extension at 72 °C for 1 min. The resulting PCR products were resolved on a 1% (w/v) agarose gel containing 10 mg/ml ethidium bromide and photographed under UV illumination.

**Single cell calcium assay**

The \([\text{Ca}^{2+}]_i\) was quantified in single cells with the \(\text{Ca}^{2+}\)-sensitive fluorescent dye fura-2, using an InCyt Dual-Wavelength Fluorescence Imaging System (Intracellular Imaging, Cincinnati, OH). Briefly, rat PCNs cultured on poly-D-lysine-coated coverslips were incubated with 2.5 mM fura-2-acetoxymethylester at 37 °C for 30 min in physiological salt solution (PSS) containing (mM) NaCl 138, KCl 5, CaCl₂ 2, MgCl₂ 1, HEPES 10, glucose 10, pH 7.4, and washed with PSS. The coverslips with fura-2-loaded cells were positioned on the stage of an inverted epifluorescence microscope (Nikon; model TMD) and stimulated with agonist at 37 °C, as described in the figure legends. The percentage of cells that responded to agonist was determined, as previously described (Kong et al., 2005). Viable cells were identified by responsiveness to carbachol and non-responding cells were eliminated.

**Overexpression of P2Y2 receptors in rPCNs**

Rat primary cortical neurons at DIV7 expressing very low levels of endogenous
P2Y<sub>2</sub>R were transiently transfected with 1 μg of human P2Y<sub>2</sub> receptor cDNA using GenCarrier<sup>TM</sup>2 (Epoch Biolabs; Sugar Land, TX), according to the manufacturer’s instructions. The transiently transfected cells were cultured for an additional 24-48 h in Neurobasal Medium with B27-AO, and used to detect sAPPα release.

**Harvesting the cells and preparation of conditioned medium**

rPCNs were plated on 6-well plates and grown until DIV7. Cells were serum-starved and incubated in 1 ml serum free DMEM with or without various compounds for specified times as indicated in the figure legends. At the end of the incubation period, the media were collected and centrifuged at 12,000 x g for 5 min to remove cellular debris. The supernatants representing conditioned media were stored at -80 °C for future use. To measure the level of secreted APPα, 200 μl of supernatant was diluted 4:1 with 50 μl of 5X Laemmli sample buffer (187.5 mM Tris-HCl, pH 6.8, 6% (w/v) SDS, 1.8% (v/v) β-mercaptoethanol and 0.003% (w/v) bromophenol blue). In addition, the cells were washed twice with ice-cold PBS, and lysed in 2X Laemmli sample buffer (200 μl/well).

**Western blot analysis**

Samples of cell lysates and conditioned media obtained above were heated for 5 min at 65 °C, and subjected to 7.5% (w/v) SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to nitrocellulose membranes for protein immunoblotting. After overnight blocking at 4 °C with 5% (w/v) fat-free milk in TBS-T (10 mM Tris-HCl, pH 7.4, 120 mM NaCl, and 0.1% (v/v) Tween-20), membranes were incubated with either 1:1000 dilution of anti-ERK1/2, anti-phospho-ERK1/2, or
anti-actin antibodies for 2 h at room temperature, or 1:1000 dilution of anti-sAPPα overnight at 4 °C followed by incubation with HRP-conjugated anti-rabbit or anti-mouse IgG antibodies (1:1000 dilution in TBS-T containing 5% (w/v) fat-free milk) for 1 h at room temperature. Protein immunoreactivity was visualized on autoradiographic film using the LumiGlo Chemiluminescence System (New England BioLabs), according to the manufacturer’s instructions. The protein bands detected on X-ray film were quantified using a computer-driven scanner and Quantity One software (Bio-Rad, Hercules, CA). The activation levels of kinases or sAPPα release were expressed as a percentage of controls (i.e., total kinase or actin).

Statistical analysis

Results are expressed as the means ± S.E.M. of data obtained from at least 3 experiments. Statistical analysis of data was performed using Graph Pad Prism version 4.0. Statistical significance was determined by student t test between groups. Differences were considered statistically significant when p < 0.05 (*) and not significant when p > 0.05 (n.s.).

RESULTS

Upregulation of functional P2Y2R in rat primary cortical neurons by IL-1β

Several subtypes of P2 nucleotide receptor mRNA are expressed in rPCNs, including P2Y1, P2Y4, P2Y6, P2X3, P2X5, P2X6 and P2X7 (Kong et al., 2005; Weisman et al., 2005). However, P2Y2R mRNA and receptor activity are barely detectable in these cells (Weisman et al., 2005, Kong et al., 2005, Figure 1A). Since
previous studies demonstrated that IL-1β causes an increase in P2Y2R mRNA expression in mouse primary striatal astrocytes (Stella et al., 1997), we used RT-PCR analysis to examine whether this cytokine could increase P2Y2R mRNA expression in rPCNs. After overnight incubation with 0-100 ng/ml IL-1β, P2Y2R mRNA (Figure 1A-B), but not P2Y4R or P2Y6R mRNA (data not shown), was upregulated in an IL-1β dose-dependent manner. Stimulation of IL-1β-treated rPCNs with the P2Y2R agonist UTP caused an increase in [Ca2+]i (Figure 1C) and activation of the MAPKs ERK1/2 (Figure 2), indicating that functional expression of the P2Y2R is upregulated by IL-1β in rPCNs. Co-incubation of rPCNs with TNF-α and IL-1β did not further enhance the effect of IL-1β on P2Y2R-mediated calcium mobilization (data not shown) or ERK1/2 phosphorylation (Figures 2C-D).

**P2Y2R-mediated release of sAPPα from rPCNs treated with IL-1β**

The release of sAPPα from rPCNs was detected by immunoblot analysis of the cell culture media with a rabbit anti-rodent sAPPα antibody that recognizes amino acid residues 3-16 of Aβ and reacts well with APP (130 kDa) and all isoforms of sAPPα (100-120 kDa). We found that overnight treatment of rPCNs with IL-1β (1-100 ng/ml) caused a dose-dependent increase in sAPPα release from cells stimulated with 100 μM UTP (Figure 3). UTP also increased the release of sAPPα from rPCNs transfected with P2Y2R cDNA, as compared to untransfected rPCNs (Figure 4), confirming the hypothesis that UTP enhances sAPPα release from rPCNs through activation of the P2Y2R subtype.

**P2Y2R-mediated release of sAPPα is dependent on ADAM10/17**
Currently, several zinc metalloproteinases have been identified as potential \(\alpha\)-secretases including tumor necrosis factor alpha converting enzyme (TACE or ADAM17 for a disintegrin and metalloprotease 17) that catalyzes the shedding of the ectodomain of APP and other transmembrane proteins (Black et al., 1997; Moss et al., 1997), and ADAM10 and MDC9 that also catalyze sAPP\(\alpha\) production (Lammich et al., 1999; Koike et al., 1999). In IL-1\(\beta\)-treated rPCNs, UTP-induced release of sAPP\(\alpha\) was significantly inhibited by TAPI-2 (Figure 5), a competitive inhibitor of ADAM17/TACE and ADAM10 (Kaup et al., 2002). Thus, P2Y\(_2\)R-mediated APP processing in rPCNs is likely mediated by ADAM10/17.

**P2Y\(_2\)R-mediated sAPP\(\alpha\) release is independent of PKC**

P2Y\(_2\)R activation causes the phospholipase C-dependent stimulation of PKC, and the activation of several other GPCRs has been reported to induce sAPP\(\alpha\) release through PKC-dependent and -independent pathways (Nitsch et al., 1994 & 1995; Checler, 1995; LeBlanc et al., 1998). Therefore, we determined whether P2Y\(_2\)R-mediated sAPP\(\alpha\) release is dependent on activation of PKC. Results indicated that the level of UTP-induced sAPP\(\alpha\) release decreased when IL-1\(\beta\)-treated rPCNs were incubated for 30 min with GF109203 (10 \(\mu\)M), an inhibitor of PKC. However, the inhibition was not significant according to the student t test, although GF109203 significantly inhibited 1 \(\mu\)M PMA-induced release of sAPP\(\alpha\) (Figure 6). Thus, sAPP\(\alpha\) release mediated by P2Y\(_2\)R activation occurs independently of PKC.

**P2Y\(_2\)R-mediated sAPP\(\alpha\) release is dependent on PI3K activation**

The release of sAPP\(\alpha\) induced by insulin requires activation of the PI3K/Akt
pathway (Solano *et al.*, 2000). Since P2Y$_2$Rs couple to PI3K activation in many cell types (Muscella *et al.*, 2003; Kaczmarek *et al.*, 2005; Wang *et al.*, 2005), we determined whether PI3K/Akt regulates P2Y$_2$R-mediated sAPP$\alpha$ release in IL-1\$\beta$-treated rPCNs. Figure 7 shows that incubation of IL-1\$\beta$-treated rPCNs with 10 $\mu$M LY29004, a selective inhibitor of PI3K, prevents UTP-induced sAPP$\alpha$ release, but has no effect on constitutive release of sAPP$\alpha$ (Figure 7).

**Role of MAPK in P2Y$_2$R-mediated release of sAPP$\alpha$**

Previous studies in our laboratory have shown that inhibition of MAPK (*i.e.*, ERK1/2) partially inhibits UTP-stimulated sAPP$\alpha$ release in human 1321N1 astrocytoma cells (Camden *et al.*, 2005). Therefore, we investigated the role of the MAPK pathway in UTP-stimulated sAPP$\alpha$ release in IL-1\$\beta$-treated rPCNs. U0126, an inhibitor of the MAPK/ERK kinase (MEK), partially inhibited UTP-induced sAPP$\alpha$ release but not the constitutive release of sAPP$\alpha$ in IL-1\$\beta$-treated rPCNs (Figure 8). These results suggest that P2Y$_2$R-mediated sAPP$\alpha$ release in rPCNs is partially dependent on MAPK/ERK1/2 activation.

**DISCUSSION**

In the present study, we demonstrate that the pro-inflammatory cytokine IL-1\$\beta$ upregulates expression of the P2Y$_2$R in rat primary cortical neurons (rPCNs). Furthermore, we report that activation of the P2Y$_2$R in IL-1\$\beta$-treated rPCNs enhances the release of sAPP$\alpha$, a neuroprotective cleavage product of APP (Li *et al.*, 1997; Luo *et al.*, 2001; Stein *et al.*, 2004), by stimulating $\alpha$-secretase activity mediated by the
metalloproteinases, ADAM10/17. Inhibitor studies reveal that P2Y₂R-mediated sAPP α release from rPCNs requires PI3K activity and is partially dependent on MAPK/ERK1/2 activation, but independent of PKC activation.

Previous studies have demonstrated that P2Y₂R mRNA and functional activity is upregulated in stressed or injured tissue, including ligated salivary gland ducts (Turner et al., 1998), collared carotid arteries (Seye et al., 2002), and submandibular gland cells from the NOD.B10 mouse model of Sjogren's syndrome (Schrader et al., 2005). It was also reported that IL-1β induced P2Y₂R mRNA expression in vascular smooth muscle cells (SMCs; Hou et al., 2000). IL-1 binds to a specific plasma membrane IL-1 type-I receptor (IL-1RI) (Sims et al., 1993), which subsequently associates with the IL-1 receptor-accessory protein (IL-1RAcP) to initiate intracellular signals (Wesche et al., 1997). Since IL-1β release has been associated with the pathophysiology of Alzheimer’s disease (Grammas and Ovase, 2001), we speculated that cytokines could upregulate P2Y₂ receptor expression in neuronal cells. We found that endogenous P2Y₂R mRNA expression and receptor activity were very low in untreated rPCNs but were significantly enhanced in response to IL-1β treatment (Figures 1 and 2; Weisman et al., 2005), suggesting that P2Y₂R expression is regulated by transcription factors coupled to IL-1 receptor activation.

As IL-1β-induced P2Y₂R mRNA expression in vascular SMCs was dramatically enhanced in combination with TNF-α treatment (Hou et al., 2000), we also tested whether TNF-α could enhance IL-1β-induced P2Y₂R expression and function. In rPCNs, TNF-α did not significantly enhance IL-1β-induced P2Y₂R mRNA expression
Although the role of P2Y$_2$R expression in neuronal cells is poorly understood, it is better established that cytokines, including IL-1β and their receptors mediate inflammation in Alzheimer’s brain (Brugg et al., 1995; Hauss-Wegrzyniak et al., 1998). Therefore, we postulate that IL-1β-induced P2Y$_2$R expression may contribute to inflammation. However, other studies suggest that P2Y$_2$R activity in human 1321N1 astrocytoma cells can promote β-amyloid precursor protein (APP) processing (Camden et al., 2005) and therefore we investigated whether this pathway was manifested upon P2Y$_2$R upregulation in IL-1β-treated rPCNs. APP is a transmembrane glycoprotein that can be detected in most tissues but is abundantly expressed in the brain (Anderson et al., 1989). Post-translational processing of APP occurs by the action of least three proteinases called α-, β- and γ-secretases (Esler and Wolfe, 2001). Cleavage of APP by β- and γ-secretases results in the release of several protein fragments, including amyloid β (Aβ), the main component in senile plaques found in the brains of patients with Alzheimer’s disease (Martins et al., 1991).

Although sAPPα is constitutively released from cells, secretion of this protein is also regulated by neural activity and can be influenced by agonists of various receptors (Robert et al., 2001; Canet-Aviles et al., 2002; Camden et al., 2005). The studies presented here suggest that IL-1β-induced upregulation of P2Y$_2$Rs in rPCNs (Figure 3) or transfection of rPCNs with P2Y$_2$R cDNA (Figure 4) significantly increases UTP-stimulated sAPPα release. Since sAPPα release is postulated to be neuroprotective in AD (Li et al., 1997; Luo et al., 2001), we suggest that P2Y$_2$R
expression in neuronal cells may play neuroprotective as well as pro-inflammatory roles in the AD brain (Weisman et al., 2005). P2Y$_4$ receptors are endogenously expressed in rat neurons and have an agonist potency order of ITP = ATP = UTP = ATP$_7$S = 2-MeSATP = Ap$_4$A (Bogdanov et al., 1998). Therefore, it is plausible to suggest that P2Y$_4$Rs may contribute to the enhanced release of sAPP$\alpha$ evoked by UTP. In rPCNs without IL-1$\beta$ treatment, P2Y$_4$R mRNA is expressed at higher levels than P2Y$_2$R mRNA (data not shown), and therefore the P2Y$_4$R may mediate UTP-induced increases in $[\text{Ca}^{2+}]_i$, seen in 1 out of 10 rPCNs in the absence of IL-1$\beta$ stimulation (Figure 1C). However, in the absence of IL-1$\beta$ treatment, UTP did not significantly increase sAPP$\alpha$ release from rPCNs (Figure 3), suggesting that the P2Y$_4$R does not contribute to APP processing in rPCNs.

There are three major isoforms of amyloid precursor protein (APP$_{770}$, APP$_{751}$ and APP$_{695}$; Kitaguchi et al., 1988) due to alternative splicing of APP mRNA. As the predominant isoform in the brain (Tanaka et al., 1989), APP$_{695}$ has received the most attention in research on Alzheimer’s disease. The ratio of APP770:APP751:APP695 mRNA is 1:10:20 in the cerebral cortex of the brain (Tanaka et al., 1989). Compared with neurons, which express higher levels of APP$_{695}$, astrocytes synthesize APPs of higher molecular weights, as expected for the Kunitz Protease Inhibitor (KPI)-containing isoforms, APP751 and APP770. Soluble APP$\alpha$ release from rPCNs into the medium can be detected in the form of a doublet (100-120 kDa for APP 695 and APP 751; data not shown), indicating that multiple APP isoforms are present, consistent with previous reports (LeBlanc et al., 1991 & 1997; Lahiri et al., 1994;
Parvathy et al., 1998; Solano et al., 2000; Ma et al., 2005).

The data presented (Figure 5) also suggest that UTP induces APP processing in IL-1β-treated rPCNs through activation of the metalloproteinases ADAM10/17. However, other members of the adalysin family may also contribute to P2Y2R-mediated sAPPα release since micromolar concentrations of TAPI-2 used to inhibit metalloproteinase activity have been reported to inhibit members of the adalysin family other than ADAM10/17 (Parkin et al., 2002).

Stimulation of GPCRs has been shown to regulate APP processing by PKC-dependent signaling pathways (Nitsch, 1992). However, APP processing can also be regulated by increases in [Ca2⁺], and activation of PLA2, PKA and tyrosine kinases (reviewed in Mills and Reiner, 1999). In human 1321N1 astrocytoma cells expressing human P2Y2R cDNA, UTP-induced sAPPα release is independent of P2Y2R-mediated activation of PKC (Camden et al., 2005). UTP-induced sAPPα release also occurred independently of PKC activation in IL-1β-treated rPCNs (Figure 6). The MAPK signaling pathway has been implicated in the regulation of both PKC-dependent and PKC-independent APP catabolism (Mills et al., 1997; Desdouits-Magnen et al., 1998). PI3K also regulated α-secretase-dependent APP processing (Solano et al., 2000; Fu et al., 2002). It also has been reported that short-term interleukin-1β incubation increases the release of sAPPα via ERK1/2-dependent α-secretase activation in Neuroglioma U251 cells whereas PI3K activity is unnecessary (Ma et al., 2005). To test the involvement of ERK/PI3K in UTP-stimulated sAPPα release in the rPCNs, after upregulation of P2Y2Rs by
overnight IL-1β treatment, we incubated cells in serum free DMEM containing specific MEK or PI3K inhibitors followed by UTP stimulation. We found that inhibition of PI3K or MAPK/ERK1/2 activity in IL-1β-treated rPCNs significantly reduced UTP-induced sAPPα release (Figures 7 and 8). Therefore, unlike short-term effects of IL-1β, long-term IL-1β treatment can regulate UTP-induced sAPPα release in a PI3K/ERK-dependent manner, most likely involving transcriptional upregulation of P2Y2R.

The results of this study strongly suggest that IL-1β evokes functional upregulation of the P2Y2R in rPCNs and subsequent activation of the P2Y2R signaling cascade by UTP results in a significant increase in sAPPα release that is at least partially dependent on PI3K- and ERK1/2-induced activation of the metalloproteinases ADAM10/17. Together, these lines of evidence suggest that under inflammatory conditions in the brain where IL-1β accumulates, functional P2Y2R expression in neuronal cells may serve a neuroprotective role in the regulation of α-, γ-secretase-mediated APP processing. Since P2Y2R expression in glial cells has been postulated to regulate inflammatory responses that may contribute to neurodegeneration in AD (Weisman et al., 2005), future studies are required to evaluate how both neurodegenerative (i.e., glial cell-mediated inflammation) and neuroprotective (i.e., sAPPα release) responses coupled to P2Y2R activation are coordinately regulated during the progression of Alzheimer’s disease.
Figure 1. IL-1β upregulates functional expression of P2Y₂ receptors in rPCNs.

(A-B) Rat primary cortical neurons at DIV7 were treated for 24 h at 37 °C in serum-free DMEM with or without IL-1β (0 ng/ml, 1 ng/ml, 10 ng/ml, 25 ng/ml, and 100 ng/ml) and cells were harvested for RNA isolation. The effect of IL-1β treatment on the expression of P2Y₂R mRNA was determined by RT-PCR, as described in "Materials and Methods". Panel B indicates the ratio of P2Y₂R to G3PDH mRNA levels. (C) IL-1β-treated cells were loaded with fura-2 AM for measurement of [Ca^{2+}]_i and positioned on the stage of an inverted epifluorescence microscope (Nikon; model TMD), as described in the “Materials and Methods”. Then, rPCNs were incubated in PSS with UTP (100 μM), and the maximum increase in [Ca^{2+}]_i was determined, as described in the “Materials and Methods”. Results were expressed as the percentage of rPCNs responding to UTP. Data represent the means ± S.E.M. of results from three experiments, where * represents significant differences (p < 0.05), as compared to rPCNs treated without IL-1β.

Figure 2. UTP stimulates phosphorylation of ERK1/2 in IL-1β-treated rPCNs. (A, C) rPCNs were deprived of serum and treated for 24 h at 37 °C in DMEM (A) with or without IL-1β (0 ng/ml, 1 ng/ml, 10 ng/ml, 25 ng/ml, and 100 ng/ml) or (C) with or without 10 ng/ml TNF-α and/or 25 ng/ml IL-1β. The next day, the media were removed and cells were incubated for 10 min with serum-free DMEM with or without 100 μM UTP at 37 °C. Cell lysates were obtained and subjected to Western blot analysis for phosphorylated ERK1/2 and total ERK1/2, as described in "Materials and Methods". (B, D) UTP-induced ERK1/2 phosphorylation was expressed as the ratio of phosphorylated ERK1/2 to total ERK1/2 and the basal level in ERK1/2 phosphorylation in the absence of UTP was subtracted. The increase of ERK1/2 phosphorylation induced by IL-1β in rPCNs was expressed as the percentage increase over UTP-stimulated rPCNs without IL-1β-pretreatment. Data represent the means ± S.E.M. of results from three experiments, where “n.s.” represents no significant differences (p > 0.05) and where * represents significant differences (p < 0.05), as compared to rPCNs treated without cytokines.
Figure 3. Release of sAPPα is stimulated by UTP in IL-1β-treated rPCNs. (A) rPCNs were treated with or without IL-1β (0 ng/ml, 1 ng/ml, 10 ng/ml, 25 ng/ml, and 100 ng/ml) for 24 h in serum free DMEM. The next day, IL-1β was removed and cells were incubated for 2 h in serum-free DMEM with or without 100 μM UTP or 1 μM PMA, a positive control. The medium was removed and assayed for sAPPα release, whereas actin levels were determined in cell lysates, as described in "Materials and Methods". (B) UTP- and PMA-induced sAPPα release in rPCNs with or without IL-1β pretreatment is expressed relative to actin levels in cell lysates, after subtracting basal sAPPα release in the absence of agonist treatment. Data represent the means ± S.E.M. of results from at least three experiments, where * represents significant differences (p < 0.05), as compared to UTP-treated rPCNs in the absence of IL-1β pretreatment.
Figure 4. P2Y<sub>2</sub> receptor expression in rPCNs enhances α-secretase-mediated APP processing induced by UTP. (A) rPCNs were transfected with human P2Y<sub>2</sub>R cDNA, as described in “Materials and Methods”. Cells expressing P2Y<sub>2</sub>R mRNA (data not shown) were incubated for 2 h in serum-free DMEM with or without 100 μM UTP or 1 μM PMA, and sAPPα release was determined as described in “Materials and Methods”, and compared to untransfected (-) controls. Actin levels in cell lysates are shown as a loading control. (B) sAPPα release is expressed relative to actin levels in cell lysates. Data represent the means ± S.E.M. of results from three independent experiments, where * represents significant differences (p < 0.05) between the indicated sample groups.
Figure 5. A metalloprotease inhibitor prevents UTP-induced sAPP\(\alpha\) release from rPCNs. (A) rPCNs were pretreated overnight with 25 ng/ml IL-1\(\beta\) and then incubated for 30 min with or without TAPI-2 (10 \(\mu\)M) followed by incubation with or without UTP (100 \(\mu\)M) for 2 h in serum-free DMEM. The release of sAPP\(\alpha\) into the medium was analyzed, as described in “Materials and Methods”. (B) sAPP\(\alpha\) release is expressed relative to actin levels in cell lysates. Data represent the means ± S.E.M. of results from six experiments, where * represents significant differences (\(p < 0.05\)) between the indicated sample groups.
Figure 6. UTP-induced sAPPα release occurs independently of PKC activation in IL-1β-treated rPCNs. (A) rPCNs were pretreated overnight with 25 ng/ml IL-1β and then incubated for 30 min with or without GF109203 (10 µM) followed by incubation with or without UTP (100 µM) or PMA (1 µM) for 2 h in serum-free medium. Then, sAPPα release into the medium was analyzed, as described in “Materials and Methods”. (B) sAPPα release is expressed relative to actin levels in cell lysates. Data represent the means ± S.E.M. of results from three experiments, where “n.s.” represents no significant differences (p > 0.05) and where * represents significant differences (p < 0.05) between the indicated sample groups.

CHAPTER 4

EXPRESSION AND REGULATION OF P2Y\textsubscript{2} NUCLEOTIDE RECEPTORS IN RODENT BRAINS AND THE EFFECT OF CEREBRAL ISCHEMIA

ABSTRACT

Large amounts of adenosine 5'-triphosphate (ATP) released from cellular sources under pathological conditions such as ischemia may activate purinoceptors of the P2X and P2Y types. Although signaling pathways for P2Y2 receptors are well understood in both primary glial cultures and cell lines derived from various tissues, less is known about P2Y2 receptor distribution in the brain. Therefore, in the present study, in situ hybridization and RT-PCR were utilized to examine the regional expression patterns of P2Y2 receptors in adult rat/mouse/gerbil brain. P2Y2R mRNA was expressed at relatively low levels in normal rodent brain, although expression levels are similar in rat, mouse and gerbil brains. In general, more abundant P2Y2R mRNA expression was detected in the hippocampus and cerebellum. In the hippocampus, P2Y2R mRNA was detected in the dentate gyrus and to a lesser extent in the CA1 and CA3 subregions. Transient global cerebral ischemia (i.e., 5 min occlusion of the CCA) did not affect P2Y2R mRNA levels in any region of gerbil brain after various reperfusion times (4 h, 16 h and 48 h), indicating that the P2Y2R is not regulated at the transcriptional level in this ischemia model.
INTRODUCTION

Cerebral ischemia occurs when blood supply to the brain or to regions of the brain is decreased due to blockage or obstruction of cerebral blood vessels. Ischemia can result in rapid increases in the intracellular calcium concentration and release of ATP from pre-synaptic neurons followed by ATP depletion that can lead to neuronal cell death (Golstein and Kroeme, 2006).

ATP release can activate two types of purinergic receptors: ligand-gated ion channel P2X receptors and G protein-coupled P2Y receptors (Burnstock, 1980). Among the known P2 receptor subtypes, P2Y\textsubscript{2} and P2X\textsubscript{7} nucleotide receptors have gained recent attention due to their widespread distribution in neuronal cells and their roles in the regulation of cell proliferation, inflammation, and apoptosis (reviewed in Franke et al., 2006).

Recent studies showed that brain astrocytes express P2Y\textsubscript{2} receptors and that P2Y\textsubscript{2}R expression, as opposed to P2Y\textsubscript{1}R, is upregulated in freshly isolated astrocytes in hippocampus during development (Zhu and Kimelberg, 2001). Upregulation of P2Y\textsubscript{2}Rs also has been shown to occur in many other cell types, tissues and injury models as previously described (Chapter 3; Turner et al., 1997; Erlinge et al., 1998; Hou et al., 1999; Seye et al., 1997 & 2002; Shen et al., 2004; Schrader et al., 2005). Here, in situ hybridization and RT-PCR were utilized to examine the regional expression patterns of P2Y\textsubscript{2} receptor subtypes in adult rodent brain and a gerbil transient ischemia model was used to study the regulation of P2Y\textsubscript{2}R mRNA expression in response to brain ischemia.
MATERIALS AND METHODS

Materials

The RNeasy Mini Kit was obtained from Qiagen (Chatsworth, CA, USA). The cDNA Synthesis Kit and the PCR Kit were obtained from Invitrogen Life Technology (Carlsbad, California, USA). The Lig'nScribe Reaction Kit was from Ambion (Austin, TX, USA). The $^{[35}\text{S}]$-NTP RNA Labeling Kit (SP6/T7) was from Roche (Indianapolis, IN, USA). $^{[35}\text{S}]$-UTP and $^{[35}\text{S}]$-dATP were obtained from NEN (Boston, MA). All other biochemicals were obtained from Sigma Chemical Co. (St. Louis, MO, USA).

RNA extraction and RT-PCR

Different regions (i.e., hippocampus, cerebellum, cerebral cortex, brain stem and the rest of the brain) were dissected from adult rodent brain. Total RNA was extracted from tissues in four steps: a. tissue was reduced from pieces (10-100 mg) to a powder with a mortar and pestle unit containing liquid nitrogen; b. powdered tissue was dissolved in 1 ml Trizol reagent and large pieces of undissolved tissue were removed; c. 200 $\mu$l of chloroform was added to the samples, which were vortexed vigorously and centrifuged for 15 min at 12,000 x g at 4 °C; and d. the upper aqueous phase was collected and one volume of 70% (v/v) ethanol was added, mixed and RNA was purified using the Qiagen Rneasy Mini Kit (Qiagen).

cDNA was synthesized by reverse transcription using purified RNA from mouse tissues (Invitrogen Life Technology). A P2Y$_2$ receptor cDNA fragment was amplified from the mouse cDNA by PCR using a 35 cycle program (94 °C for 1 min, 60 °C of the annealing temperature for 30 sec, 72 °C for 1 min; $G3PDH$ was used as a control.
with 30 cycles and 55 °C for annealing) in the presence of 50 U/ml Taq polymerase (ThermoAce™ DNA polymerase from Invitrogen) and two P2Y2R C-terminal primers (1 μmol/l): gerbil P2Y2 forward: 5’-TGC TGC CCC TGT CCT ACG GCG TGG-3’ (1-24 of AF313448; the sequence of gerbil P2Y2R from http://www.ncbi.nlm.nih.gov/entrez/viewer.fcgi?db=nuccore&id=12751144), gerbil P2Y2 reverse: 5’-AGG TTG GTG TAG AAG AGG AAG CGC-3’ (241-218 of AF313448). The following primers for human G3PDH were used as a control: sense 5’-TGA AGG TCG GAG TCA ACG GAT TTG GT-3’, antisense 5’-CAT GTG GGC CAT GAG GTC CAC CAC-3’. PCR products were resolved by 2% agarose gel electrophoresis, and P2Y2/G3PDH ratios were determined by densitometry.

**Gerbil global cerebral ischemia model**

Adult male Mongolian gerbils (60–80 g body weight) (Charles River, Wilmington, MA) were given free access to water and lab chow and maintained at 22 ± 2 °C with a constant humidity under a 12:12 h light:dark cycle. Gerbils were randomly divided into a sham control group, an ischemic group and an ischemic group with resveratrol. For some animals in each group, resveratrol (Sigma, St. Louis, MO) was dissolved in corn oil and injected intraperitoneally (30 mg/kg body weight) immediately after and 24 h after induction of ischemia by occlusion of both common carotid arteries (CCAs), as previously described (Wang et al., 2002). Sham controls also were injected with the same volume of corn oil and underwent similar surgical procedures without occlusion of the CCAs. The animal protocol was approved by the University of Missouri-Columbia Animal Care and Use Committee.
(Protocol #1741). Experiments were in accordance with the NIH Guidelines for the Care and Use of Laboratory Animals. To eliminate gerbils that have communicating arteries, regional cerebral blood flow (rCBF) was monitored before and after clamping the bilateral CCA using a laser Doppler flowmeter (MBF3D, Moor Instruments, Devon, UK). Gerbils showing a decrease in rCBF of less than 80% upon occlusion of CCAs were excluded from subsequent analyses (Wang et al., 2002).

**Tissue sections**

Normal/sham/ischemic rodent brains were removed, wrapped in parafilm and aluminum foil and placed in tightly capped 50 ml conical tubes, unless the brains were sectioned immediately. Stored tissue was cut into 12 µm-thick sections, thaw-mounted onto microscope slides, dried briefly on a warm plate (32 °C; 1 min), and kept in 100-place slide boxes at -80°C until in situ hybridization.

**Probes**

To generate P2Y₂R specific riboprobes for in situ hybridization, a T7 promoter adapter was ligated to the 247-bp P2Y₂R fragment amplified by reverse transcription-polymerase chain reaction (RT-PCR) with the Lig'nScribe Reaction Kit (Ambion). Antisense and sense riboprobes were obtained by in vitro transcription with [³⁵S]-UTP using the [³⁵S]-NTP RNA Labeling Kit (SP6/T7) (Roche). P2Y₂R oligoprobes were prepared by labeling the following oligonucleotides with [³⁵S]-dATP at the free 3’ hydroxyl end using terminal deoxynucleotidyl transferase: 1. 5’-GAT GGC GTT GAG GGT GTG GCA ACT GA G GTC AAG TGA TCG GAA GGA-3’;
and 2. 5’-CGT TCC AGG TCT TGA GGC GGC ACA GGA AGA TGT AGA)-3’.

In situ hybridization

Hybridization was performed overnight at 55 °C for the riboprobes and 37 °C for the oligoprobes in a humidified chamber, as described previously (Simonyi et al., 2002). Briefly, normal rodent brain or ischemic hippocampal sections were fixed in situ by 4% (v/v) paraformaldehyde for 5 min, then rinsed with 2 × SSC. Next, sections were dehydrated and delipidated with the following graded series of ethanol (EtOH) dilutions and chloroform: 1 min in 50% EtOH, 1 min in 70% EtOH, 1 min in 80% EtOH, 2 min in 95% EtOH, 1 min in 100% EtOH, 5 min in Chloroform, 1 min in 100% EtOH, and 1 min in 95% EtOH. The sections then were air-dried. Sections to be used as negative controls were treated with RNase A solution (10 mg RNase/50 ml, 0.5 M NaCl, 0.01 M Tris, 0.001 M EDTA, pH = 8) at 37 °C for 30 min, then washed in 1 X SSC three times for 1 min each, dehydrated twice with 70% EtOH for 2 min, twice with 80% EtOH for 2 min, and twice with 90% EtOH for 2 min. Next, sections on slides were hybridized under coverslips in a humidified chamber at 55 °C overnight in 25 μl hybridization buffer containing approximately 1-2 × 10^6 dpm radioactive probe (antisense or sense) and 1 μl nonradioactive probe. After sections were cooled to room temperature, coverslips were removed in 4 × SSC, washed 4 times in 4 × SSC for 15 min each at room temperature, and incubated in RNase buffer for 30 min at 37 °C to reduce nonspecific background. Then, sections were washed, dehydrated, and exposed to a radiosensitive film (Kodak Biomax MR-1).
**Image analysis and data analysis**

Using standard autoradiographic techniques, the sections on slides were apposed to radiosensitive film (Kodak Biomax MR-1) with $[^{14}C]$-labeled calibration standards (American Radiolabeled Chemicals, St. Louis, MO) for 1 week and then developed. The standards comprised of 16 $[^{14}C]$-labeled standards on glass slides with 0.002 to 3.58 $\mu$Ci/g radioactivity were used to construct linear calibration curves of tissue-equivalent radioactivity ($\mu$Ci/g) relative to the film optical density. Based on the standard curve, microdensitometry of film autoradiograms was performed on the signal over different hippocampal subregions using the BIOQUANT True Color Windows 95 software version 2.50, as previously described (Shelat et al., 2006). The amount of $[^{35}S]$-labeled probe radioactivity ($\mu$Ci/g) within various hippocampal subregions was quantitated, from which background radioactivity/optical density was subtracted. The average density measured from various hippocampal subregions fell within the linear range of the standards.

Data are expressed as means ± S.E.M. The number of animals in each group varied between 15 and 23 except for the resveratrol-treated groups which contained 7 animals. Statistical differences between sample groups were evaluated by ANOVA and Student-Newman-Keuls test, where $p < 0.05$ was considered to be significant.

**RESULTS**

$P2Y_2R$ mRNA expression in rodent brains

$P2Y_2$ receptor riboprobes were designed from a cloned 247 base pair sequence of
gerbil P2Y\(_2\)R cDNA that has high similarity to the rat gene sequence. Two oligoprobes complementary to different regions of the cDNA were prepared. These probes and the antisense riboprobe produced identical patterns of hybridization when tested on adjacent sections (data not shown). Sense riboprobe and RNase treatment were used as two negative controls for nonspecific binding. Both the RNase-treated tissue labeled with oligoprobes (or antisense probe) and the untreated ischemic tissue labeled with sense riboprobe had clean backgrounds, which indicated weak nonspecific binding. P2Y\(_2\) receptor mRNA was expressed at relatively low levels in various brain regions, but was most abundant in hippocampus and cerebellum in rat, mouse and gerbil brains (Figure 1). Similar \(P2Y_2R\) expression patterns in adult rat brains were demonstrated by RT-PCR (Figure 2A). P2X\(_7\) receptor mRNA was detected in all brain regions (i.e., cerebral cortex, cerebellum, brain stem, hippocampus and the rest of the brain), but expression was highest in hippocampus, cerebellum and cortex (Figure 2B). Other P2Y receptor mRNAs were expressed in rat hippocampus (P2Y\(_1\)) and cortex (P2Y\(_1\) and low levels of P2Y\(_6\)) (Figure 2C).

\(P2Y_2\) mRNA expression in the gerbil hippocampus after transient ischemia

Transient ischemia induced by a 5-minute occlusion of CCAs in the gerbil causes selective and delayed neuronal death (DND) of CA1 pyramidal neurons associated with activation of surrounding astrocytes in the hippocampus (Kirino, 1982). Regulation of P2Y\(_2\)R mRNA expression in response to ischemia was studied in hippocampal subregions of gerbil brain after a 5 min CCA occlusion followed by various reperfusion times (Figure 3). In control hippocampus, the hybridization signal
was relatively high in dentate gyrus as compared to the CA1 and CA3 regions (Figure 4).

Since increased expression of P2Y$_2$ receptors has been associated with inflammation, tissue damage and disease (Weisman et al., 2005; Seye et al., 2006), P2Y$_2$ mRNA expression was quantified in gerbil hippocampus after ischemic insult/reperfusion. Statistical analysis showed that there was no significant change of P2Y$_2$ mRNA expression in the CA1 region during early stages of transient ischemic injury (5 min occlusion + 4 h/16 h/48 h reperfusion; Figure 3 A-C). P2Y$_2$ receptor mRNA levels were not significantly changed in other hippocampal subregions in response to CCA occlusion followed by 4-48 h reperfusion (Figure 4). Neurons in the hippocampal CA1 region were depleted 3 days after occlusion/reperfusion, whereas microglia and astrocytes proliferated in this brain region. Although P2Y$_2$R mRNA was hard to detect in the CA1 region (Figure 3D), results appear to indicate that P2Y$_2$R mRNA expression is not transcriptionally regulated by ischemia in this animal model.

*Resveratrol administration does not affect P2Y$_2$R mRNA levels in normal or ischemic gerbil brain*

Increased oxidative stress has been implicated in the mechanisms of DND following cerebral ischemic insult (Kirino, 2000). As a polyphenolic compound enriched in grape and red wine, resveratrol has drawn wide attention lately as an effective anti-oxidative agent (Ray et al., 1999; Hung et al., 2000; Huang et al., 2001; Giovannini et al., 2001; Fremont, 2003). Resveratrol has been shown to protect
against global cerebral ischemic injury in gerbils (Wang et al., 2002) and neurotoxicity induced by kainic acid (Wang et al., 2004). Therefore, we tested whether resveratrol, a polyphenolic antioxidant enriched in grape, has an effect on the P2Y₂R mRNA expression and/or promote neuroprotective signaling through activation of P2Y₂R in gerbil ischemic brain. Mongolian gerbils were divided into three groups: a sham control group, an ischemic group and ischemic group treated with resveratrol. Results indicated that injection of resveratrol significantly prevented DND (data not shown), but had no effect on the P2Y₂R mRNA expression levels in ischemic animals (Figure 5).

**DISCUSSION**

This study demonstrated similar expression patterns for P2Y₂ receptor mRNA in the brains of adult rats, mice and gerbils. P2Y₂ receptor mRNA was expressed at relatively low levels in various brain regions, but was most abundant in hippocampus and cerebellum. P2X₇ receptor mRNA was detected in all brain regions, but was expressed at highest levels in hippocampus, cerebellum and cortex.

Rapid release of ATP from pre-synaptic vesicles in the early stages of ischemic injury can activate P2 nucleotide receptors and is likely to be an important signal in the ischemic process (Franke and Illes, 2006b). The P2Y₂ receptor subtype can mediate cellular responses typically associated with cell proliferation and inflammation that may contribute to ischemic responses in cells (Erb et al., 2006). Moreover, upregulation of the P2Y₂R subtype has been found in cells and tissue exposed to stress and injury (Koshiba et al., 1997; Turner et al., 1997 and Seye et al., 2007).
Thus, it is important to investigate how P2Y$_2$Rs are regulated in neuronal cells in response to brain ischemia.

Extensive evidence demonstrates that ischemia and reperfusion causes the upregulation of P2X (P2X$_{2, 4, 7}$) and P2Y (P2Y$_1$) receptor subtypes in neurons and glial cells in specific brain regions (Franke and Illes, 2006b) and suggests a direct role for these receptors in the pathophysiology of cerebral ischemia \textit{in vitro} and \textit{in vivo} (Cavaliere et al., 2002, 2003, 2004; Franke et al., 2004a). In contrast, the present studies show that P2Y$_2$ receptor mRNA expression is not significantly altered in gerbil brain hippocampus at different ischemic stages (\textit{i.e.}, 4-48 h of reperfusion after a 5 min CCA occlusion).

Resveratrol is a polyphenolic antioxidant enriched in grapes and red wine that has been found to reduce ischemia/reperfusion injury in both non-neural organs such as rat hearts and kidney (Ray et al., 1999; Hung et al., 2000; Giovannini et al., 2001) and in the rat focal cerebral ischemia and gerbil transient global cerebral ischemia models (Huang et al., 2001; Wang et al., 2002). The present studies indicate that resveratrol injection did not alter P2Y$_2$R mRNA levels in ischemic gerbil brain. Therefore, resveratrol mediates neuroprotective signaling independent of the transcriptional activation of \textit{P2Y}_2R in gerbil ischemic brain, although further studies are warranted to examine the mechanisms underlying transcriptional regulation of P2Y$_2$R expression and the effect of antioxidants.
Figure 1. P2Y$_2$ receptor mRNA expression in the adult rodent brain. The expression pattern of P2Y$_2$ nucleotide receptor mRNA in gerbil/rat/mouse brains was identified by *in situ* hybridization with a [$^{35}$S]-labeled riboprobe, as described in “Materials and Methods”. Rnase A-treated sections were used as a negative control. HI, hippocampus; CE, cerebellum; CO, cerebral cortex.

CHAPTER 5

GENERAL DISCUSSION

ATP and other extracellular nucleotides are released from a variety of cell types in the central nervous system including neurons, glia, endothelium, and blood cells (Bergfeld et al., 1992; Ciccarelli et al., 1999; Ahmed et al., 2000; Ostrom et al., 2001). Nucleotides have been suggested to act as a neuroprotective growth factor by regulating cell differentiation, proliferation, and survival, as well as a neurotoxic signal in promoting neuronal degeneration and cell death (Franke and Illes, 2006). Extracellular nucleotides activate two classes of P2 nucleotide receptors (P2X\textsubscript{1-7} ligand-gated ion channels and P2Y\textsubscript{1,2,4,6,11-14} G protein-coupled receptors; Sak and Webb, 2002; Inbe et al., 2004). P2X/Y receptor families are widely distributed and developmentally expressed in the central nervous system (CNS), as previously described (reviewed in Franke and Illes, 2006b), which suggests a role for purinergic signaling in the development of brain structures. Further studies show that P2 nucleotide receptors play important physiological and pathophysiological roles in a variety of biological processes including neuronal growth, survival and brain injury (Franke et al, 2006a & b).

The upregulation of P2 nucleotide receptor expression has been reported after ATP/NGF/cytokine stimulation (Rathbone et al., 1999; D’Ambrosi et al., 2001), and in tissue injury and disease models of the CNS and other tissues (Collo et al., 1997; Moore et al., 2000; Seye et al., 2002; Cavaliere et al., 2003 &2004; Parvathenani et
In Alzheimer’s disease and brain ischemia, in vivo and in vitro studies have shown that P2X₂ (in ischemia), P2X₄ (in ischemia), P2X₇ (in ischemia and AD) and P2Y₁ (in AD) receptor expression is upregulated in specific cell types, as described in Table 1.

The P2Y₂R can be equipotently activated by ATP and UTP to stimulate G protein-coupled signaling pathways, and to transactivate growth factor receptors (Liu et al., 2004) and integrins, e.g., α₅β₃/β₅ (Erb et al., 2001; Wang et al., 2005; Liao et al., 2007). Studies also indicate that upregulation of the P2Y₂R occurs in a variety of cell and tissue types after injury (Seye et al., 2002; Schrader et al., 2005; Kunzli et al., 2007). The P2X₇R is distinguished from other P2XR subtypes due to its inability to form heteromeric channels, the presence of an extended C-terminal tail; the high concentrations of agonist required for activation, and the ability to form pores that enable the passage of large molecular weight molecules (Sperlagh et al., 2006). P2X₇R functions in the CNS include the regulation of synaptic transmission and neuronal cell death (Sperlagh et al., 2006).

This dissertation describes the functional expression and regulation of P2Y₂ receptor activity by IL-1β in primary neurons and the upregulation of the P2Y₂R in tissue injury models. Results obtained demonstrate that P2Y₂Rs mediate the release of neuroprotective sAPPα, whereas P2X₇Rs mediate apoptosis in rat primary cortical neurons. However, further studies are needed to better understand the roles of P2Y₂ and P2X₇ nucleotide receptors in neurodegeneration, such as the mechanism whereby IL-1β induces upregulation of P2Y₂R expression, the role of P2Y₂Rs in APP
translocation/phosphorylation and Aβ production induced by caspase-dependent APP processing, and the relationship of P2X7R-mediated neuronal apoptosis to the AD phenotype.

Major contributions and significance

The scientific significance of this dissertation work to the field is summarized below.

1) **P2Y2 receptor expression was identified**: a) in rat primary cortical neurons (Kong et al., 2005 & manuscript in preparation); b) in adult rodent brains; and c) in brain hippocampus at different stages of cerebral ischemia (unpublished data; Weisman et al., 2005; Chapter 4). 2) **Upregulation of the P2Y2R occurs after IL-1β treatment in rPCNs and after collar placement around rabbit carotid arteries.** In rat primary cortical neurons, IL-1β treatment increased P2Y2R mRNA expression and receptor activity in a dose-dependent manner (Kong et al., manuscript in preparation; Chapter 3). Other studies demonstrate the upregulation of P2Y2Rs in endothelial and smooth muscle cells of collared rabbit carotid arteries (Appendix-1; Seye et al., 2002 & 2003; reviewed in Seye et al., 2005). 3) **P2Y2R activation enhances α-secretase-dependent amyloid precursor protein processing in rPCNs.** Previous studies from our lab with the human 1321N1 astrocytoma cell line that does not express endogenous P2Y2Rs, indicated that transfection with human P2Y2R cDNA enables UTP to induce α-secretase-dependent APP processing (Camden et al., 2005). The current studies (Chapter 3) confirmed that P2Y2Rs upregulated by IL-1β treatment of primary cultures of rat cortical neurons mediate neuroprotective APP
processing, and suggest that P2Y$_2$R expression in neurons could be targeted to suppress neurodegenerative Aβ deposition in Alzheimer’s disease (Kong et al., manuscript in preparation). 4) **P2X$_7$Rs mediate apoptosis of rPCNs.** In rat PCNs, functional expression of P2X$_7$Rs was detected and activation of the P2X$_7$R was found to mediate caspase-dependent apoptosis and studies presented identified the signaling pathways involved (Kong et al., 2005; Chapter 2). 5) **P2Y$_2$Rs mediate UTP-induced intimal hyperplasia in collared rabbit carotid arteries.** Our studies demonstrate for the first time that functional P2Y$_2$R upregulation leads to the development of neointimal hyperplasia in collared rabbit carotid arteries, a response associated with atherosclerosis and restenosis after angioplasty (Seye et al., 2002; Appendix-1). Further studies showed that the P2Y$_2$ receptor also mediates UTP-induced vascular cell adhesion molecule-1 expression in coronary artery endothelial cells that promotes the binding of monocytes leading to vascular inflammation (Seye et al., 2003). 6) **Studies in collaboration with other lab members identified P2Y$_2$ receptor signaling pathways involving integrin interactions and demonstrated that antagonists of CD39 ectonucleotide triphosphate diphosphohydrolase (E-NTPDase) activity also inhibit P2Y$_2$R functions** (Erb et al., 2001; Gendron et al., 2002; Wang et al., 2005). Studies with the E-NTPDase inhibitor BG0136 showed that this compound displays inhibitory activity towards the P2Y$_2$R expressed in human 1321N1 cells, which suggests that BG0136 may represent a novel P2 nucleotide receptor antagonist (Gendron et al., 2002; Appendix-2). Other studies demonstrate that the P2Y$_2$ nucleotide receptor interacts with αv integrins through an RGD domain
in the first extracellular loop of the P2Y₂R. These P2Y₂R/α₅ integrin interactions were shown to be required for Gα₅-mediated signal transduction that regulates astrocyte migration (Erb et al., 2001; Appendix-3).
APPENDIX

BRIEF REVIEW OF OTHER RESEARCH PROJECTS
A-1. FUNCTIONAL P2Y<sub>2</sub> NUCLEOTIDE RECEPTORS MEDIATE URIDINE 5'-TRIPHOSPHATE-INDUCED INTIMAL HYPERPLASIA IN COLLARED RABBIT CAROTID ARTERIES

ABSTRACT

Extracellular UTP induces mitogenic activation of smooth muscle cells (SMCs) through binding to P2Y<sub>2</sub> nucleotide receptors. Previous reports also show that P2Y<sub>2</sub> receptor mRNA is upregulated in intimal lesions of rat aorta, but it is unclear how P2Y<sub>2</sub> receptors contribute to development of intimal hyperplasia. In the present studies, we used a silicone collar placed around rabbit carotid arteries to induce vascular injury and intimal thickening. Collar placement caused rapid upregulation of P2Y<sub>2</sub> receptor mRNA and receptor activity (i.e., UTP-induced increases in the intracellular calcium concentration) in medial SMCs before appearance of neointima. Neointimal development was significantly enhanced by perivascular infusion of UTP (100 µmol/L) and neointima were infiltrated by macrophages. UTP also stimulated osteopontin expression in situ in collared arteries and in cultured SMCs in a dose-dependent manner. Furthermore, P2Y<sub>2</sub> antisense oligonucleotide inhibited osteopontin expression induced by UTP suggesting that this response to UTP was specifically mediated by P2Y<sub>2</sub> receptor subtype. In conclusion, these findings indicate for the first time a role for the UTP/ATP receptor, P2Y<sub>2</sub>, in development of intimal hyperplasia associated with atherosclerosis and restenosis.
INTRODUCTION

Atherosclerosis is an immunoinflammatory process that involves complex interactions between the vessel wall and blood components primarily affecting the large conduit arteries. Endothelial dysfunction is thought to be a key factor in the development of vascular disease (Ross 1993; Ferns et al., 1991; Wang et al., 1992). Previous studies suggest that an intact endothelium is important in maintaining a low proliferative state of smooth muscle cells (SMCs) under normal conditions (Gordon, 1986). In arterial injury, nucleotides are released from endothelial cells, SMCs, and various blood cells and can bind to P2 receptors to modulate proliferation and migration of SMCs, which is known to be involved in intimal hyperplasia that accompanies atherosclerosis and postangioplasty restenosis (Erlinge et al., 1993). The aim of this study was to determine whether activation of the P2Y$_2$R promotes intimal hyperplasia under conditions that maintain the vascular endothelium.

MATERIALS AND METHODS

Cell culture

Rabbit SMCs obtained from normal carotid arteries by enzymatic dissociation were maintained in culture and used from passages 4 to 6. Phosphorothioate-modified oligonucleotides to rabbit P2Y$_2$R were synthesized and purified by Integrated DNA Technologies (ADT). Sequences including translation initiation site were as follows: sense 5'-GGGCAATGGGCACCTCTCCCTCACCTG
ACA-3', antisense 5'-TGTCAGGTGAGGGAAGAGTGCCATTGCC-3'.
Sequences were checked for uniqueness with the National Center for Biotechnology Information’s Basic Local Alignment Search Tool (BLAST). SMCs were incubated with 0.1 or 1 µmol/L P2Y2R sense or antisense S-oligonucleotides for 6 h in serum-free medium containing 1.4% DOTAP liposomal reagent (Roche Diagnostics). Serum-free medium was added, and cells were cultured for an additional 20 h. FITC-conjugated P2Y2R antisense and sense oligonucleotides were used to quantify cellular oligonucleotide uptake by SMCs. Cells were rendered quiescent by a 24 h incubation in serum-free medium before stimulation with nucleotides.

Collar implantation

The collared rabbit carotid artery model was employed to induce arterial stress (Figure 1). Protocols conformed to Animal Care and Use guidelines of the University of Missouri-Columbia. New Zealand White rabbits (42 animals) were anesthetized subcutaneously with ketamine (33 mg/kg body weight) and xylazine (7 mg/kg body weight). Rabbits were maintained under respiration with oxygen and 0.2% isoflurane. A nonocclusive, biologically inert, flexible silicone collar (20 mm long; inlet/outlet diameter 1.8 mm; Silicone MED-4211, Nusil Technology) was placed around a carotid artery (Figure 1), and the contralateral artery was sham operated, i.e., isolated from surrounding connective tissue and exposed to similar stretch. Arteries were collected at day 3 (n = 12), 7 (n = 14), or 14 (n = 14). Two collars per animal were implanted in another series of experiments, and each was
connected to an osmotic minipump (Alzet 2 ML2; Alza Corporation) implanted subdermally in the thoracic region. The pump continuously delivered (5 µl/h) UTP (100 µmol/l) or PBS (mmol/l: NaCl 154, Na₂HPO₄ 8, NaH₂PO₄ 2, EDTA 0.2) for 3 (n = 14), 7 (n = 14), and 14 (n = 14) days. After surgery, analgesic (Buprenex; 0.1 to 0.5 mg/kg body weight) was administered.

**Immunoblotting**

Cultured cells were solublized in 2X Laemmli sample buffer (120 mmol/L Tris-HCl, pH 6.8, 2% SDS, 10% sucrose, 1 mmol/L EDTA, 50 mmol/L dithiothreitol, 0.003% bromophenol blue). Rabbit aortas were homogenized with a polytron homogenizer in buffer containing 0.9% NaCl, 20 mmol/L Tris-HCl, pH 7.6, 1 mmol/L PMSF in 0.2% Triton X-100. Equivalent amounts of protein (100 µg) were subjected to 10% SDS-PAGE and transferred to nitrocellulose membranes for immunoblotting. Detection of OPN (Chemicon International) was performed with rat anti-human OPN (1:1000 dilution) and horseradish-peroxidase-conjugated goat anti-rat IgG (1:1500 dilution) as primary and secondary antibodies, respectively. For signal normalization, membranes were reprobed with anti-mouse α-tubulin antibody (1:1000 dilution; Santa Cruz Biotechnology).

**RESULTS**

*Effect of local UTP application on OPN expression*

Immunoblots of sham-operated arteries indicated lack of OPN expression (Figure 2A, Lane 5), whereas collared arteries at day 14 expressed OPN (Figure 2A, Lane 2).
Local UTP infusion greatly increased OPN expression (Figure 4A, Lane 4) compared with PBS (Figure 2A, Lane 3).

**UTP-induced OPN expression is mediated by P2Y$_2$Rs in SMCs**

UTP exposure for 8 h stimulated OPN expression in vascular SMCs (Figure 2B) in a dose-dependent manner (Figure 2C). ATP and 10% FBS (positive control) induced OPN expression, whereas ADP, 2-MeSATP, and UDP did not (Figure 2B), which suggests that P2Y$_2$Rs mediate OPN expression. To conclusively demonstrate the role of P2Y$_2$Rs, SMCs incubated with 0.1 or 1 µg of P2Y$_2$R antisense or sense oligonucleotides were stimulated with 50 µmol/L UTP for 8 h. Antisense (Figure 2D, Lanes 5 and 6) but not sense (Figure 2D, Lanes 2 and 3) P2Y$_2$R oligonucleotides inhibited UTP-induced OPN expression in SMCs.

**DISCUSSION**

Proliferation of SMCs is a hallmark of vascular diseases such as atherosclerosis and restenosis following angioplasty (Hanke et al., 1990). Nucleotides released from various arterial and blood cells (Di Virgilio and Solini, 2002) can bind to P2 nucleotide receptors. In our present studies, *in vivo* experiments showed that the P2Y$_2$ receptor was functionally upregulated in both SMCs and endothelial cells after collar implantation (Seye et al., 2002). Moreover, intimal thickening of collared rabbit carotid arteries was greatly enhanced by *in situ* UTP application (Seye et al., 2002) and was closely associated with osteopontin (OPN) expression in medial SMCs (Figure 2A). *In vitro* studies showed that both UTP and ATP increased OPN
expression in cultured SMCs whereas ADP, UDP, and 2-MeSATP were ineffective (Figures 2B-C), which suggests a role for the P2Y\textsubscript{2}R in which ATP and UTP are equipotent, and is confirmed by the inhibition of UTP-induced OPN expression in cultured SMCs after P2Y\textsubscript{2}R antisense oligonucleotide treatment (Figure 2D).

Extracellular nucleotides may also cause cell recruitment by inducing lymphocyte and macrophage adhesion to human pulmonary artery endothelial cells, as demonstrated \textit{in vitro} (Parker \textit{et al}., 1996). In collared rabbit carotid arteries, we found that local UTP delivery via an osmotic pump induced intimal accumulation of macrophages mediated by P2Y\textsubscript{2} receptors (data not shown; Seye \textit{et al}., 2002).

In conclusion, these studies demonstrate for the first time that extracellular UTP and the P2Y\textsubscript{2}R contribute to the development of arterial lesions associated with atherosclerosis and restenosis.
Figure 1. Collared rabbit carotid artery model. New Zealand White rabbits (42 animals) were anesthetized and (A) a nonocclusive, biologically inert, flexible silicone collar (20 mm long; inlet/outlet diameter 1.8 mm; Silicone MED-4211, Nusil Technology) was (B) placed around a carotid artery, and the contralateral artery was sham operated, *i.e.*, isolated from surrounding connective tissue and exposed to similar stretch.
Figure 2. Nucleotide-induced OPN expression in collared carotid arteries and SMC cultures. A. Collared arteries connected to an osmotic minipump were continuously infused with UTP or saline for 14 days. Lane 1, control (kidney); 2, collar without infusion; 3, collar with PBS, 4, collar with UTP; 5, sham-operated artery. Blots were reprobed with anti-α-tubulin antibody. B-C. SMCs were stimulated with 10% FBS or (B) 50 μmol/L nucleotide or (C) the indicated UTP concentration. Immunoblot analysis was performed with anti-OPN antibodies. Data represent 3 (A) or 5 (B) experiments. D. SMCs incubated with P2Y_{2}R sense or antisense S-oligonucleotides for 6 h in DMEM containing 1.4% DOTAP liposomal reagent were cultured for an additional 16 h in serum-free medium before 50 μM UTP treatment. Cells were incubated with serum-free medium (Lane 1); 0.1 (Lane 2) or 1 (Lane 3) μg of sense oligonucleotide; serum (Lane 4); or 0.1 (Lane 5) or 1 (Lane 6) μg of antisense oligonucleotide.

**ABSTRACT**

Extracellular nucleotides initiate various cellular and physiological responses through P2 nucleotide receptors. Another important factor affecting extracellular nucleotide signaling is ecto-nucleoside triphosphate diphosphohydrolase (NTPDase; CD39) now considered as the main ecto-nucleotidase responsible for degrading tri- and diphosphonucleosides to monophosphate derivatives through sequential hydrolysis. Since the concentration and duration of extracellular nucleotides are key regulators of P2 nucleotide receptor function, the influence of ecto-nucleotidases is always considered as one of the major ways to modulate P2 receptor function. In the present studies, the NTPDase inhibitor BG0136 and several cell model systems including COS-7 cells, HEK cells and human 1321N1 astrocytoma cells stably transfected with \( P2Y_2R \) cDNA were employed to understand the complex interrelationship between P2\( Y_2 \) receptors and ecto-nucleotidases. Treatment with 350 \( \mu \)M BG0136 resulted in a 30-50% decrease in UTP-stimulated ERK1/2 activity in COS-7, HEK cells and P2\( Y_2 \)-transfected 1321N1 cells. In contrast, the COS-7/CD39 cell transfectants demonstrated a decrease in UTP-stimulated inositol phosphate release compared to native COS-7 cells. The variable effects of BG0136 on P2\( Y_2 \) receptor signal propagation in cells expressing CD39 cDNA observed in our studies suggests that BG0136 may represent a new P2\( Y_2 \)R antagonist.
INTRODUCTION

It was suggested that inhibition of the ecto-nucleotidases responsible for the hydrolysis of extracellular nucleotides could be an important factor in the modulation of purinergic signaling. This study concerns the inhibition of NTPDase and its possible impact on different physiological systems. Several enzymes are involved in the metabolism and control of extracellular nucleotide concentrations (Beaudoin et al., 1996 & 2000; Gordon 1986; Zimmermann 1992 & 2000; Ziganshin et al., 1994; Plesner et al., 1995; Vlajkovic et al., 1998). The enzymes described above may also play an important role in the dephosphorylation of extracellular nucleotides (Zimmermann 2000; Beaudoin et al., 1996; Culic et al., 1990). In the past, modulation of nucleotide-induced cell signaling was focused on nucleotide receptors. Ecto-nucleotidases, more particularly the E-NTPDases family of ecto-enzymes, are now considered as potential new targets for P2 receptor modulation. Inhibition or modulation of E-NTPDases may prolong the effect of nucleotides at their respective receptors and/or modulate cell-to-cell interaction (Imai et al., 1999; Clifford et al., 1997; Dzhandzhugazyan et al., 1998). New molecules have been synthesized to inhibit ecto-nucleotidases and particularly the E-NTPDases, such as P2 receptor agonists/antagonists and molecules related to the suramin-Evans blue families. Based on the structure-activity requirements, as described by Wittenburg et al. (Wittenburg et al., 1996), we report here the possible antagonistic property of BG0136 (1-naphthol-3, 6-disulfonic acid, disodium salt) towards the P2Y2 receptor.
MATERIALS AND METHODS

Materials

Fetal bovine serum (FBS) was obtained from Hyclone (Logan, UT, USA). Dulbecco’s Modified Eagle’s medium (DMEM), penicillin (100 units/ml), and streptomycin (100 units/ml) were obtained from Gibco-BRL (Carlsbad, CA, USA). Rabbit anti-rat ERK1/2, horseradish peroxidase (HRP)-conjugated goat anti-rabbit IgG, and HRP-conjugated goat anti-mouse IgG antibodies were obtained from Santa Cruz Biotechnology (Santa Cruz, CA, USA). PERK antibody was obtained from Cell Signaling Technology (Beverly, MA, USA). The Precision Plus Protein Standards and nitrocellulose membranes (0.45 mm) were obtained from Bio-Rad (Hercules, CA, USA). LumiGLO chemiluminescent substrates were obtained from New England Biolabs (Beverly, MA, USA). Nucleotides and all other biochemicals were obtained from Sigma Chemical Co. (St. Louis, MO, USA).

Cell Culture and Transfection

Human 1321N1 astrocytoma cells (Parr et al., 1994), African Green Monkey Kidney Fibroblasts (COS-7 cells) and Human Embryonic Kidney (HEK) cells were cultured in DMEM (GIBCO BRL) containing 5% FBS, 100 U/ml penicillin, and 100 μg/ml streptomycin. Cells were maintained at 37 °C in a humidified atmosphere of 5% CO₂ and 95% air. The retroviral vector, pLXSN, was used for stable expression of the P2Y₂R construct in 1321N1 cells as described previously (Erb et al., 1995). In brief, the recombinant P2Y₂R-pLXSN construct was used to transfect PA317 amphotrophic packaging cells for production of viral vectors. Then, 1321N1 cells
were infected with the viral vectors and selected for neomycin resistance with 1 mg/ml G418 (GIBCO BRL).

IP Assay

To measure accumulation of IPs, COS-7 cells with or without expression of CD39 were plated in 12-well dishes and incubated in the presence or absence of the specified antibodies for 24 h in 0.7 ml serum-free and inositol-free DMEM containing 2 µCi of [³H]-inositol (20 Ci/mmol). The cells were washed three times and incubated for 30 min at 37 °C in 1 ml of LiCl solution (15 mM glucose, 25 mM Hepes, 110 mM NaCl, 5 mM KCl, 1.8 mM CaCl₂, 0.9 mM MgCl₂, and 30 mM LiCl) followed by stimulation with 0.1 µM UTP for 10 min. The reactions were stopped by aspiration and cell extracts were obtained by addition of 0.3 ml of ice-cold 10% perchloric acid for 15 min. The extracts were neutralized with 0.6 ml of 2 M NaOH and 225 mM Hepes. The IPs in the neutralized extracts were separated from inositol and glycerophosphoinositol on Dowex columns, as described previously (Berridge et al., 1983). Radioactivity in the IP fraction was determined by liquid scintillation spectrometry using Ecolume scintillation fluid.

Western blot analysis

Cells cultured in 6-well plates were treated with nucleotides in the presence or absence of inhibitors as indicated. The cells were washed twice with ice-cold PBS, and lysed for 5 min in 200 ml of ice-cold lysis buffer (20 mM Tris-HCl, pH 7.5, 2% (w/v) sodium dodecyl sulfate (SDS), and 1 mM sodium orthovanadate). Lysate (30
mg of protein) was added to Laemmli sample buffer (187.5 mM Tris-HCl, pH 6.8, 6% (w/v) SDS, 1.8% (v/v) β-mercaptoethanol and 0.003% (w/v) bromophenol blue). Samples were heated for 5 min at 96 °C, and subjected to 7.5% (w/v) SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to nitrocellulose membranes for protein immunoblotting. After overnight blocking at 4 °C with 5% (w/v) fat-free milk in TBS-T (10 mM Tris-HCl, pH 7.4, 120 mM NaCl, and 0.1% (v/v) Tween-20), membranes were incubated with either 1:1000 dilution of anti-ERK1/2 or anti-phospho-ERK1/2 antibodies for 2 h at room temperature, followed by incubation with HRP-conjugated anti-rabbit or anti-mouse IgG antibodies (1:1000 dilution in TBS-T containing 5% (w/v) fat-free milk) for 1 h at room temperature. Protein immunoreactivity was visualized on autoradiographic film using the LumiGlo Chemiluminescence System (New England BioLabs), according to the manufacturer’s instructions. The protein bands detected on X-ray film were quantified using a computer-driven scanner and Quantity One software (Bio-Rad, Hercules, CA). The activation levels of ERK1/2 were calculated as a percentage of control (i.e., total ERK1/2).

RESULTS

To determine the effect of CD39 on P2 nucleotide receptor-mediated signaling pathways, COS-7 and HEK cells were transfected with CD39. UTP-stimulated inositol phosphate release (Figure 1A) and ERK phosphorylation (Figure 1B and 2) were both inhibited in CD39-transfected COS-7 and HEK cells compared to untransfected cells, indicating that the expression and activation of E-NTPDase by
UTP inhibited UTP-stimulated P2Y₂ nucleotide receptor signaling pathways. A recently developed compound, 1-hydroxynaphthalene-3, 6-disulfonic acid (BG0136) has been shown to inhibit bovine spleen NTPDase with a Ki of 350 μM. However, BG0136, the inhibitor of E-NTPDase also inhibited UTP-stimulated ERK phosphorylation in both CD39-transfected COS-7 and HEK cells (Figure 1B and 2), indicating the possible direct interaction of BG0136 with the P2Y₂ nucleotide receptor.

To investigate whether BG0136 could interact with P2 purinoceptors, human 1321N1 astrocytoma cells which do not express endogenous P2Y₂Rs were stably transfected with human P2Y₂R. Pretreatment of cell transfectants with 350 μM BG0136 resulted in greater than 50% inhibition of ATP- and UTP- stimulated ERK1/2 phosphorylation in hP2Y₂-1321N1 cells (Figure 3). Since this cell line has been found to have very little ectonucleotidase activity (Gendron et al., 2002), it appears that BG0136 could be either acting directly on the P2Y₂ receptor or on some other component(s) in the ERK signaling pathway.

Altogether, our results obtained with BG0136 and CD39-transfected COS-7, HEK and hP2Y₂-1321N1 cells showed that transfection with ectonucleotidase inhibits UTP-stimulated signaling mediated by P2Y₂ nucleotide receptors, including inositol phosphate release and ERK1/2 activation, whereas BG0136 inhibits UTP/ATP-stimulated ERK phosphorylation mediated by P2Y₂Rs, possibly by acting as a P2Y₂ receptor antagonist. Hence, even if BG0136 displays inhibitory activity towards E-NTPDase, it should be considered as a potential new P2Y₂ nucleotide
receptor antagonist. However, further studies need to be done with this compound to determine its molecular specificity for P2 nucleotide receptor subtypes and ectonucleotidases.
Figure 1. Effect of BG0136 on UTP-stimulated inositol phosphate (IP) release and ERK1/2 activation in COS-7 cells with or without CD39 transfection. African Green Monkey Kidney Fibroblast (COS-7) Cells with (CD39/COS7) or without CD39 transfection were incubated with 350 μM BG0136 for 5 min at 37 °C, followed by stimulation with 10 μM UTP at 37 °C for the indicated time. IP release was measured by inositol assay and the phosphorylation of ERK1/2 was determined by Western blot analysis in which total ERK1/2 levels served as a loading control.
Figure 2. Effect of BG0136 on UTP-stimulated ERK1/2 activation in HEK cells with or without CD39 transfection. Human Embryonic Kidney (HEK) cells with or without CD39 transfection were incubated with 350 μM BG0136 for 5 min at 37 °C, followed by stimulation with 10 μM UTP at 37 °C for the indicated time, and the phosphorylation of ERK1/2 was determined by Western blot analysis in which total ERK1/2 levels served as a loading control.

A-3. AN RGD SEQUENCE IN THE P2Y₂ RECEPTOR INTERACTS WITH αᵥβ₃ INTEGRINS AND IS REQUIRED FOR G₀-MEDIATED SIGNAL TRANSDUCTION

ABSTRACT

The P2Y₂ nucleotide receptor (P2Y₂R) contains the integrin-binding domain arginine-glycine-aspartic acid (RGD) in its first extracellular loop, raising the possibility that this P2Y₂R interacts directly with an integrin through its RGD domain. In this project, we tested whether an antibody raised against the αᵥ integrin subunit could interfere with UTP-stimulated P2Y₂R signal transduction such as inositol phosphates accumulation. Human 1321N1 cells expressing the P2Y₂R were incubated in the presence or absence of specific anti-αᵥ integrin antibody for 24 h in serum-free and inositol-free DMEM containing [³²H]-inositol. Cells were then used to measure UTP-stimulated inositol phosphate (IP) release. The results indicate that overnight treatment with anti-αᵥ antibody partially inhibits IP formation, consistent with the partial inhibition of UTP-induced FAK and ERK activation by anti-αᵥ antibody and the decreased calcium response mediated by RGE mutant P2Y₂Rs as compared to wild-type P2Y₂Rs (Erb et al., 2001). In conclusion, these studies suggest that interaction of αᵥ integrins with the P2Y₂R is important for optimum P2Y₂R activation.
INTRODUCTION

As a G protein-coupled nucleotide receptor, activation of the P2Y$_2$R stimulates PLC-dependent production of IP$_3$ and DAG followed by calcium release and PKC activation. P2Y$_2$Rs can also bind to growth factor receptors (GFRs) through SH3-binding domains in the C-terminal tail of the P2Y$_2$R and cause transactivation of GFR signaling pathways. The present studies explore protein complex formation between integrins and the P2Y$_2$ nucleotide receptor (P2Y$_2$R), a G$_o$- and G$_q$-coupled P2 nucleotide receptor subtype that is equipotently stimulated by ATP or UTP and mediates various cellular responses (Erb et al. 1993; Boarder et al. 1995). RGD has been found in various integrin ligands, (Clark and Brugge 1995; Frenette and Wagner 1996) as the core recognition sequence for many integrins, including $\alpha_V\beta_3$, $\alpha_V\beta_5$, $\alpha_V\beta_{11}$, $\alpha_S\beta_1$, and $\alpha_{IIb}\beta_3$ (Hynes 1992). Studies by Erb et al. (Erb et al., 2001) with P2Y$_2$R-transfected cells indicated that a mutation of the RGD motif in the wild-type P2Y$_2$R to RGE decreases receptor colocalization with $\alpha_V$ integrins by 10-fold and the RGE-mutant P2Y$_2$R requires 1,000-fold higher agonist concentrations than the wild-type P2Y$_2$R to phosphorylate FAK, activate ERK, and initiate the PLC-dependent mobilization of intracellular Ca$^{2+}$. Furthermore, pertussis toxin, an inhibitor of G$_{i/o}$ proteins, partially inhibited Ca$^{2+}$ mobilization mediated by the wild-type P2Y$_2$R, but not by the RGE mutant, suggesting that the RGD sequence is required for P2Y$_2$R-mediated G$_o$ but not G$_q$ activation. To address the possibility that the P2Y$_2$R interacts with a specific integrin, here it was investigated whether an
antibody raised against the $\alpha_V$ integrin subunit could interfere with UTP-stimulated P2Y$_2$R signal transduction.

**MATERIALS AND METHODS**

*Materials*

Fetal bovine serum (FBS) was obtained from Hyclone (Logan, UT, USA). Dulbecco’s Modified Eagle’s medium (DMEM), penicillin (100 units/ml), and streptomycin (100 units/ml) were obtained from Gibco-BRL (Carlsbad, CA, USA). Anti–human $\alpha_V$ monoclonal antibody (mAb) was purchased from Zymed Laboratories. Anti–human $\alpha_3$ mAb was purchased from Santa Cruz Biotechnology, Inc. Nucleotides and all other biochemicals were obtained from Sigma Chemical Co. (St. Louis, MO, USA).

*Cell culture and transfection*

Human 1321N1 astrocytoma cells (Parr *et al.*, 1994) were cultured in DMEM (GIBCO BRL) containing 5% FBS, 100 U/ml penicillin, and 100 $\mu$g/ml streptomycin. Cells were maintained at 37 °C in a humidified atmosphere of 5% CO$_2$ and 95% air. The retroviral vector, pLXSN, was used for stable expression of the $P2Y_2R$ constructs in 1321N1 cells, as described previously (Erb *et al.*, 1995). In brief, the recombinant $P2Y_2R$-pLXSN construct was used to transfect PA317 amphotrophic packaging cells for production of the viral vectors. Then, 1321N1 cells were infected with the viral vectors and selected for neomycin resistance with 1 mg/ml G418 (GIBCO BRL).

*IP assay*
To measure accumulation of IPs, 1321N1 cells expressing the P2Y₂R were plated in 12-well dishes and incubated in the presence or absence of the specified antibodies for 24 h in 0.7 ml serum-free and inositol-free DMEM containing 2 μCi of [³H]-inositol (20 Ci/mmol). The cells were washed three times and incubated for 30 min at 37 °C in 1 ml of LiCl solution (15 mM glucose, 25 mM Hepes, 110 mM NaCl, 5 mM KCl, 1.8 mM CaCl₂, 0.9 mM MgCl₂, and 30 mM LiCl) followed by stimulation with 0.1 mM UTP for 10 min. The reactions were stopped by aspiration and cell extracts were obtained by addition of 0.3 ml of ice-cold 10% perchloric acid for 15 min. The extracts were neutralized with 0.6 ml of 2 M NaOH and 225 mM Hepes. The IPs in the neutralized extracts were separated from inositol and glycerophosphoinositol on Dowex columns, as described previously (Berridge et al., 1983). Radioactivity in the IP fraction was determined by liquid scintillation spectrometry using Ecolume scintillation fluid.

RESULTS

P2Y₂R-mediated signaling is inhibited by anti-α₅V antibodies

We investigated whether an antibody raised against the α₅V integrin subunit could interfere with UTP-stimulated P2Y₂R signal transduction. To analyze the effect of this antibody on the P2Y₂R calcium signaling pathway, we measured IP formation since inositol 1, 4, 5-trisphosphate (IP₃) is the second messenger for intracellular calcium mobilization (Weisman et al., 1998). The results indicated that overnight treatment with anti-α₅V antibody partially inhibited IP formation induced
by UTP (Figure 1), consistent with the decreased calcium response seen for the RGE mutant P2Y₂ receptor as compared with the wild-type P2Y₂R (data not shown; Erb et al., 2001). Anti-α₃ integrin antibody had no effect on the ability of the P2Y₂R to stimulate calcium signaling (Figure 1). These findings suggest that interaction of α₅ integrin with the P2Y₂R is important for optimum P2Y₂R activation.
Figure 1. Effect of anti-integrin antibodies on P2Y$_2$R-activated IP formation in 1321N1 cells. Human 1321N1 cells expressing wild-type P2Y$_2$Rs were incubated for 24 h with or without 100 µg/ml of the indicated antibody. The cells were then stimulated with 1 µM UTP for 10 min. Generation of IP is expressed as the percentage of maximum stimulation with UTP after background subtraction (backgrounds for control, $\alpha_3$-treated, and $\alpha_v$-treated samples were 18,462 ± 1,090, 15,670 ± 1,000, and 30,450 ± 3,650 dpm, respectively).

Qiongman Kong was born on August 25, 1979, in Hubei Province, People's Republic of China. After attending public schools in Xianning, Hubei Province, she started her college studies in the Special Class for the Gifted Young at the University of Science and Technology of China in Hefei, Anhui Province. In July of 1999, she graduated with a B.S. degree in Molecular and Cellular Biology from the School of Life Sciences. She then joined the graduate program in the Interdisciplinary Neuroscience Program at the University of Missouri-Columbia. As of September 2007, she will start her postdoctoral training in the Department of Neuroscience at The Ohio State University in Columbus, Ohio.
