Biomarker Test for Lou Gehrig's Disease Useful in Diagnosing Canine Neurodegenerative Disease

Mizzou researchers seek clinical trial participants for further treatment study

May 03, 2017

COLUMBIA, Mo. – In 2009, Joan Coates, a veterinary neurologist, along with other researchers at the **University of Missouri** and the Broad Institute at MIT/Harvard, found a genetic link between degenerative myelopathy (DM) in dogs and amyotrophic lateral sclerosis (ALS), or Lou Gehrig's disease in people. Now, MU researchers Coates and [Michael Garcia](#), an associate professor in the [Division of Biological Sciences](#), have found that a biomarker test that helps diagnose ALS also can assist with determining a diagnosis for degenerative myelopathy.

Coates is seeking clinical trial participants to evaluate a treatment for canine DM.

In dogs, DM is an older adult onset disease that can eventually lead to paralysis. The neurodegenerative disease has been confirmed in more than 30 pure bred dog breeds, such as Pembroke Welsh corgis, German Shepherd Dogs and boxers, as well as mixed breed dogs. The current genetic test for DM can be useful to breeders and veterinarians in identifying risk for the disease; however, it has limitations when diagnosing DM.

“DM is a diagnosis of exclusion, meaning that veterinarians must rule out all other diseases that mimic it before coming to a final diagnosis,” said Coates, a professor in the [MU Department of Veterinary Medicine and Surgery](#). “This requires expensive diagnostic procedures such as MRIs of the spinal cord. Now that we know that DM and ALS are related, we are studying ways to diagnose and measure disease progression with similar diagnostic modalities used in ALS patients.”

ALS can be tested using phosphorylated neurofilament heavy proteins (pNF-H) that are released into spinal fluid and blood in humans with ALS. These biomarkers are released during the degeneration of spinal tissues making them a good indicator that ALS is present. Coates and co-principal investigator Garcia tested whether the diagnostic tool could be used in canines.

“I was very excited by the idea that there could be another model that might have many more strength than the existing models,” Garcia said. “So this was a natural fit for me.”

Cerebrospinal fluid and blood samples were collected from DM-affected dogs, including dogs that had a confirmed diagnosis as well as dogs in early stages of the disease. pNF-H concentrations from those samples were compared to samples from age-matched normal dogs and dogs with mimicking diseases.

“We found a significant difference in the DM affected dogs,” Coates said. “pNF-H levels were increased in the cerebrospinal fluid of the DM-affected dogs relative to the control groups, indicating that the human ALS test could be used to diagnose DM. These results will enable us to ‘scale up’ the test to make it more accessible to veterinary community.”

Collecting cerebrospinal fluid from patients is more complicated than a blood test, but is less expensive compared to an MRI to make a presumptive DM diagnosis, Coates said. Nonetheless, pNF-H may serve as a diagnostic tool for diagnosis of DM.

Coates also is conducting clinical trial research for treatment of DM. The goals of the therapies being tested is to slow the progression of neurologic signs of DM and improve quality of life. These therapies are in collaborations with other ALS researchers and funded by the ALS Association and National Institutes of Health. The clinical trials are taking place at the MU Veterinary Health Center (VHC) Small Animal Hospital. To inquire about enrolling a dog, contact Coates at coatesj@missouri.edu.

Collaborations among human health and veterinary clinicians and researchers highlights the multidisciplinary, One Health/One Medicine initiative at Mizzou. The concept is a worldwide strategy for expanding interdisciplinary collaborations and communications in all aspects of healthcare for humans and animals where biomedical research discoveries and expanding the scientific knowledge base lead to faster improvements benefitting both humans and our pets.

The study, “[Cerebrospinal Fluid Levels of Phosphorylated Neurofilament Heavy as a Diagnostic Marker of Canine Degenerative Myelopathy](#),” was published in the *Journal of Veterinary Internal Medicine*. [Christine Toedebusch](#), a veterinary neurology resident and doctoral candidate, was lead author on the study. The study was funded in part by the [American Boxer Charitable Foundation](#) and the [American Kennel Club Canine Health Foundation](#) (Grant #2165). The content is solely the responsibility of the authors and does not necessarily represent the official views of the funding agencies.
