ACC is largely a silent disease unless hormone secretion leads to an early diagnosis; 70% of cases have metastasized at the time of diagnosis and common sites include liver, lung, bone and peritoneum. Adult disease tends to be more aggressive and has a poorer prognosis than ACC in children. Treatment includes surgical resection and adjuvant therapy (mitotane and possible radiation). Prognosis is often poor and is related to the completeness of surgical resection and the presence of distant metastases. Several small patient series, published in recent years, suggest an improvement in survival over time.
